Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ¼ H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression, to serve as a hydraulic tourniquet, an aspirator and intermittent siphon, to demonstrate the ascent of liquids in exhaustive tubes; to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1586.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1596.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published in Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil, a pair of one-pint Leyden jars, and an inductance coil, and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained, with the help of diagrams, in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT illustrated with diagrams. Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE. Illustrated with diagrams, Scientific American Supplement 1624.

HOW TO MAKE A MAGIC LANTERN. Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained, with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplement 1494, 1049, and 1406.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE, Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522, and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement, 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1566, and 1582.

ANEROID BAROMETERS. Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1464.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

Order from your newsdealer or from

MUNN & CO., Inc. 361 Broadway, New York

[illegible] up or acceleration of the engine.

A tachometer has recently been perfected by Mr. Mellor Reese Hutchison, in which these defects are avoided by very simple and dependable means.

The accompanying illustration shows a merchant marine generating set of this electrical tachometer, installed in the shaft alley of a steamer.

The large split sprocket wheel *B*, of proper diameter to conform to the shaft *A*, is firmly clamped thereto. A Morse silent chain *C*, engaged by the sprocket wheel *B*, drives a similar sprocket wheel *D* mounted on a countershaft *E*, which forms part of the tachometer generating set. The rotation of this small sprocket is transmitted to the flywheel *F*, keyed to the countershaft *E*, through the intermediary of two opposite coiled spiral springs *G*, *H*. Inside the rim of the flywheel *F* and on the end opposite to the spiral springs *G*, *H*, gear teeth are cut which engage two pinions. These pinions respectively actuate magnetos *XY*. It is seen that any momentary fluctuation in the rotation of sprocket *D*, occasioned by variations in the angular velocity of the main shaft *A*, are smoothed out by the springs *G*, *H*, imparting to the flywheel *F* and countershaft *E* a steady average speed. To protect the springs *G*, *H*, against rupture from sudden reversal of rotation of main shaft *A*, stop pin *K* is mounted on the flywheel, and engages radial arm *L*, mounted on the sprocket wheel *D*, thereby preventing more than one-half an independent revolution of the countershaft. This one-half revolution is sufficient to take care of practical conditions on marine equipments.

The magnetos *XY* are of the inductor type. The armatures and the pole pieces are stationary. 1 is a permanent magnet of finest steel, properly aged to insure absolute permanence. 2 2 are the pole pieces of soft iron attached thereto. 3 is a stationary shuttle armature, on which is winding 4. Rotating between the pole pieces and the armatures is the soft iron inductor 5. As the inductor is rotated an alternating electromotive force is generated in the armature, two cycles per revolution.

The magneto is so designed that the voltage is directly proportional to the speed of rotation of the inductor, over a wide range. Therefore, the faster the propeller shaft turns, the higher the voltage directly proportional thereto.

It will be noted there are no commutators or brushes, the armature being stationary and the leading-out wires soldered to the main line wires. Therefore no error can creep in from increase of resistance of contacts.

The indicators are alternating-current voltmeters of the dynamometer type, i. e., having a moving coil and stationary coils.

In present practice, however, alternating-current voltmeters read but one way, with the zero on the left of the scale. A tachometer, specially for marine use, must show direction of rotation of main shaft as well as the speed. In the design of this, therefore, the zero is at the center, deflections of the pointer to the left indicating speed of rotation of the propeller shaft astern, and to the right ahead.

The pointer of the indicator is deadbeat at its reading, and is not influenced by the rolling or pitching of the ship. Provision is also made to protect the instrument against concussion or atmospheric disturbance from heavy gunfire.

In the naval type each indicator is entirely independent of all the rest, being connected to its own pair of magnetos; hence, should one indicator be shot away or otherwise damaged, it will not affect the reading of any of the other indicators.

In the merchant marine type, however, this is not deemed [illegible]

(Concluded from page 168.)

of magnetos supplying all the indicators, which are connected in multiple.

A very important fact in Mr Hutchison's system is the use of an exceedingly small current value and low voltage hence, in the event of the indicators being located in proximity to ammunition, should the circuit be opened by the breaking of a wire or otherwise, the resultant spark is barely perceptible and cool, therefore incapable of igniting anything. Should the line become short-circuited, no heating effect whatever is produced and no damage done to the magnetos, as they can run for an indefinite time on dead short circuit No effect is produced on the compass by the current in the wires and taken all in all the system seems to meet every requirement of accuracy and safety

◆

POWERFUL HOISTING AND CONVEYING MACHINE

(Continued from page 156.)

in the machinery house at the pier end of the bridge, the power from which is transferred to the moving gear wheels by a line of shafting on top of the bridge thence to lines of shafting down the pier and shear supports, and thence by a proper train of gears to the wheels.

The moving gear mechanism is attached to the operating mechanism by means of friction clutches, so arranged that the motion of the crane may be made in either direction at the will of the operator Further provision is made for disconnecting the gearing in order to skew the bridge within the limits given

The main operating mechanism for the bridge is located in the machinery house, and consists of two drums. Each of these drums is mounted loose on its supporting shaft Each drum is controlled by a Brown friction clutch and a band friction brake The drums are connected one to the other through an equalizing gear mechanism which is equipped also with a powerful foot brake so that the two main operating drums may be made to rotate in opposite directions with the same speed This feature of connecting the two drums is one of the all important points in the Brown two-drum operating mechanism The main operating machinery is further arranged to operate from the intermediate shaft the bridge crane moving gear mechanism to which the supporting truck wheels are connected by shafting and gearing This mechanism is controlled also by a powerful clutch and band friction foot brake

In further connection with the two main operating drums is a small closing drum which, in conjunction with the two main drums controls all of the motions of hoisting and lowering the load and traveling the trolley The trolley, which in reality forms also a part of the main hoisting mechanism, is specially designed to operate in conjunction with the drum arrangement above described In general, this trolley consists of a steel structural frame mounted on four turned cast-steel track wheels arranged to run on the trolley runway of the bridge crane. In the trolley there are mounted specially-designed drums which run loose on their supporting shafts. The large section of each drum on the trolley is connected to the main hoisting drums in the machinery house in the following manner

One length of wire rope will connect, from the under side one of the main hoisting drums to the top side of one of the large sections of the trolley drums. The under side of this trolley drum is connected by wire ropes to the top side of the other main hoisting drum The top side of this same hoisting drum is connected by suitable cable to the top side of the other trolley drum, and likewise this trolley drum from the under side is connected to the underside of the other main hoisting drum. By this arrangement of ropes, if one of the main

$3,000.00 Worth of Automobile for $2,000.00

THERE are two ways of buying an automobile. One is to pay *too little* The other is to pay *too much*

If you want to get all of the real pleasure and satisfaction out of motoring you've got to have *the automobile* to do it with

Try to economize too much in the purchase of your car—and you do it at a sacrifice of *your* pleasure the pleasure of *your family* and *your friends*

It is now needless—since the advent of the Haynes Model 19—to invest a young fortune for the *most satisfactory car made*

Pay $2,000.00 for this new Haynes car, and you get everything that's worth having on an automobile You get style workmanship—mechanism—all around quality

Pay *more* and you make an unnecessary investment Pay *less*—and you're apt to get an unsatisfactory car short-lived and full of troubles one that you will want to dispose of (at a sacrifice) as soon as you get a taste of the pleasures of motoring

Did you ever stop to think that the man who has run one of the cheaper cars, who *sells* it and gets a larger more roomy elegant machine such as our Haynes Model 19 never enjoys riding in the cheaper car again? He has *graduated* from the cheap-car class.

As motor cars become more popular and people become more educated on the question of buying—more people are buying *right* the *first* time

It's expensive evolution in car buying to work up through the cheaper and smaller cars to a *satisfactory* car at last—because there's bound to be a loss *on every small car you sell—to say* nothing of the expense of maintenance while you own it

This Model 19 is intended for two classes of buyers—those who are *through experimenting* and those who want to *avoid* it.

HAYNES

It is distinctly a car for *conservative* buyers.

No matter *what price* you intend paying for a car you ought to get the facts about this car *before you buy*

After you have seen it and ridden in it and controlled it you will appreciate its *positive $3,000.00 value*

If you want something better (and cheaper) than a one season car and a car that you can feel *proud* of in the company of even the highest-priced cars let us send you the facts about this Model 19 and tell you when you can see it and have a demonstration

Use this coupon for your convenience

Instructive Scientific Papers
ON TIMELY TOPICS
Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P Ford A paper of immense practical value to the architect and builder SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER By Harold Busbridge An excellent presentation of modern views fully illustrated SCIENTIFIC AMERICAN SUPPLEMENT 1500

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER By N Monroe Hopkins. Fully illustrated SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT VISION SPECTROSCOPES. By T H Blakesley M A An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No 1493

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865 The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home, SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641

Price 10 Cents each, by mail

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

BUSINESS OPPORTUNITIES

AGENTS WANTED.—$2 [illegible] sample outfit free. 50 per cent. profit. Credit given. Premiums. Freight paid. Chance to win $500 in gold extra. Let the largest wholesale agency house in the United States start you in a profitable business without one cent of capital. Experience unnecessary. Write for free outfit at once. McLean Black & Co., Inc. 40 Beverly St. Boston, Mass.

Inquiry No. [illegible].—Wanted to buy nickeloid for buttons.

FOR SALE. Model Printing Press Co. Established over 40 years. Excellent opportunity for machinist. Mail order trade throughout the world. Will sell at a bargain. Model Printing Press Co., Chambersburg, Pa.

WILL MANUFACTURE OR SELL PATENT for a new carbide generator for house or town plant. Machines now out doing excellent service. Address O. Hassadar Seaford, Long Island.

Inquiry No. [illegible]. For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

MAIL ORDER GOODS WANTED.—Western firm wants quotations from manufacturers of quick-selling household specialties suitable for canvassers. Address Box 10, Victoria, B. C.

Inquiry No. [illegible]. For the manufacturers of silk paper.

PATENTS FOR SALE

FOR SALE. Patent No. [illegible]. Metal shelf with folding brackets, as illustrated in Scientific American of August [illegible], 19[illegible]. Now being manufactured and marketed in New York and surrounding States with good results. Rights to distant states can be obtained by responsible manufacturers by applying to The Dahl Mfg. Co., [illegible] W 14th Street, New York.

Inquiry No. [illegible].—Wanted the address of Worthington Boiler Co.

FOR SALE Patent No. [illegible]. Purse or the like, chain purses, neck chains, fobs, belts, etc. For further information and particulars, Address P. O. Box [illegible], Attleboro, Mass.

Inquiry No. [illegible].—For parties who manufacture the Western Stump borer for boring stumps.

FOR SALE—Patent No. [illegible], rowing appliances works perfectly every boatman needs a pair. Make us an offer. James & Deacon Velasco, Texas.

Inquiry No. [illegible].—For manufacturers of machinery for making fly screens.

FOR SALE.—Patent No [illegible]. Metal telephone pole. Most durable, strongest, lightest and cheapest pole in existence. Address R. J. Newhall, Waupaca, Wis.

SALESMEN WANTED

SALESMAN WANTED to handle an exceptionally attractive real estate and timber proposition, which can be sold on annual, semi-annual or monthly installments. We furnish inquiries and strong literature. Capable, aggressive, energetic man can make desirable connection with largest and strongest house in its line in the country. Sacramento Valley Imp. Co., St. Louis Mo.

Inquiry No. [illegible].—For the address of the Windsor Mfg. Co. manufacturers of waterproof collars and cuffs.

HELP WANTED

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition, and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden Pres., The National Co-operative Real Estate Company, Suite [illegible], Marden Building, Washington, D. C.

Inquiry No. [illegible]. Wanted the address of the Cobonfiet Motor Co.

SUCCESSFUL Gasoline Light Salesman to handle the only instantaneous lighting system known to science. No alcohol, step ladders, torches, matches or time wasted. Pull the chain and they light instantly. For home and commercial lighting. Write for territory. Small capital required. Gloria Light Co., 128 Wash'n Blvd. Chicago.

Inquiry No. [illegible].—Wanted machines that make accordion dress plaiting (steam).

YOUNG MAN graduate of some school in mechanical engineering for position in woodworking plant in small Tennessee town. Good opportunity for advancement. State experience, if any, and salary. Answer "Position," Box [illegible], New York.

Inquiry No. [illegible]. For manufacturers of machinery for manufacturing denatured alcohol.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., List Department, Box 773, New York.

Inquiry No. [illegible]. For the address of manufacturers of mortars and pestles that are used by druggists.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., List Department, Box 773, New York.

Inquiry No. [illegible]. Wanted the address of the manufacturers of Cypress wash tubs.

Inquiry No. [illegible]. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

Inquiry No. [illegible]. For information regarding shoes not made of leather but similar to the same and are as durable.

Inquiry No. [illegible]. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

Inquiry No. [illegible].—Wanted the address of the manufacturers of bread or cake boxes.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

Inquiry No. 9007.—Wanted a tin churn for churning milk that has a wire spring at top and bottom of churn and operated by pressing the wire springs.

Inquiry No. [illegible].—Wanted the address of the manufacturer of the "Leroy" showcard holder, a device which is held to the outside of a show window by rubber cups.

Inquiry No. 9010.—Wanted to buy a "[illegible] Help-a-Phone."

Inquiry No. 9011.—For the manufacturers of a patent sewing needle that is made to slip over the thread; the eye is split so as to open and receive the thread.

Inquiry No. 9013.—Wanted to buy papier maché boxes in the shape of water melons, colored to resemble melons, etc.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

Inquiry No. 9015.—Wanted the address of the manufacturers of a solid link chain made without welding, made in brass, several different sizes, made on an automatic machine.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

Inquiry No. 9017.—Wanted the address of manufacturers or dealers in card board plaster or wood pulp for plastering.

Inquiry No. 9018.—Wanted, the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9019.—Wanted, address of The Old Town Canoe Co.

Inquiry No. 9020.—Wanted the addresses of the manufacturers of metal novelties.

(Continued from page 169.)

hoisting drums is connected through its clutch mechanism to the driving shaft, and the other main hoisting drum is allowed to work through the equalizing gear mechanism loose on its supporting shaft, the motion of the drums will be in opposite directions and with the same speed, and when working under this condition the motion produced on the trolley drums will be *nil*, thus giving to the trolley a motion or translation along its supporting runway and by the reversal of the motion of the main hoisting drums the trolley will be traveled in an opposite direction. Further if the main hoisting drums are both rotated in the same direction the drums on the trolley will be rotated in opposite directions with respect to one another and by the proper reeving of the ropes from the small drums on the trolley, the suspended load may be raised and lowered by the reversal of the motions of the main hoisting mechanism. When equipped with grab bucket, the opening and closing of the same is accomplished by the ropes leading from one of the main trolley drums. The shell lines from the grab bucket are attached to the other of the main trolley drums and for the same reasons as given above the bucket may be raised and lowered. But to carry out the motion of opening and closing the two main hoisting drums in the machinery house are held stationary and the small auxiliary hoisting and closing drum is put in operation. This drum is connected to a sliding loop attachment located at a convenient point on the bridge structures and in such a way that the ropes leading from the large section of the drum controlling the opening and closing lines of the bucket are reeved through this sliding loop mechanism and by the operation of this closing drum the one set of lines leading to the trolley is lengthened while the other set is shortened. By this means the one drum, controlling the opening and closing of the bucket, may be rotated in either direction by the proper operating of the closing drum above referred to. From this description it will be seen that in reality the main hoisting mechanism consists of the two main hoisting drums and the auxiliary closing drum, all of which drums are under the complete control of the operator, and work in conjunction with one another to properly carry out the various motions of the trolley and its load.

In the operation, however, of the scoop bucket, with which the above bridge crane is equipped, only one main drum on the trolley is used, this being the drum operating the shell lines of the grab bucket. The lines leading from the small drum sections of this main drum are arranged to work in parallel and carry the shovel bucket. All of the clutches, brakes, etc., going to make up the main operating machinery are connected to the operator's cage by suitable rods and levers so that the entire mechanism is under the complete control of one operator.

The 200 horse-power motor and electrical equipment is designed so that dur-

(Concluded on page 17[illegible].)

Practical and Instructive Scientific Books

AGRICULTURE.—The New Agriculture. By T. Byard Collins. 12mo. 374 pages, 106 illustrations. $[illegible]

A popular outline of the many changes which are revolutionizing the methods of farming, and the habits of farm life. It is one of the most practical treatises on the subject which has ever been issued.

ALCOHOL.—Industrial Alcohol. Its Manufacture and Uses. By John K. Brachvogel. 8vo., 528 pages, 107 illustrations. $[illegible]

A practical treatise based on Dr. Max Maercker's "Introduction to Distillation," as revised by Drs. Delbruck and Lange, comprising raw material, malting and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat, and power production, a statistical review, and the United States law.

AMATEUR MECHANICS.—Home Mechanics for Amateurs. By George M. Hopkins. 12mo. 370 pages, 326 illustrations. $1.50

This is a thoroughly practical book by the most noted amateur experimenter in America. It appeals to the boy as well as the more mature amateur. Holidays and evenings can be profitably occupied by making useful articles for the home or in the building of small engines or motors or scientific instruments.

AMUSEMENTS.—The Scientific American Boy. By A. Russell Bond. 12mo., 317 pages, 340 illustrations. $2.00

This is a story of outdoor boy life, suggesting a large number of diversions which, aside from affording entertainment, will stimulate in boys the creative spirit. In each instance complete practical instructions are given for building the various articles.

COMPRESSED AIR.—Compressed Air. Its Production, Uses and Application. By Gardner D. Hiscox. 8vo. 665 pages, 540 illustrations. $5.00

The most complete book on this subject. It treats on its physical and operative properties, and is written by an expert. Taken as a whole it might be called an encyclopedia of compressed air.

DIES.—Their Construction and Use for the Modern Working of Sheet Metals. By Joseph V. Woodworth. 8vo. 384 pages, 505 illustrations. $3.00

A most useful book and one which should be in the hands of all engaged in the press working of metals, treating on the designing, constructing, and use of tools, fixtures and devices, together with the manner in which they should be used in the power press, for the cheap and rapid production of sheet metal articles.

ELECTRICITY.—The Standard Handbook for Electrical Engineers. Written and compiled by a Staff of Specialists. Second edition, corrected. 12mo. 1285 pages, 1260 illustrations. Bound in flexible morocco. $4.00

A new pocketbook consisting of twenty sections, each written by a specialist of engineering experience and containing the latest data and information regarding standard electrical practice.

ELECTRICITY.—Electrician's Handy Book. By T. O'Conor Sloane. 761 pages, 556 illustrations. Handsomely bound in red leather pocket book style. $3.50

This work is intended for the practising electrician who has to make things go. Although the principles of electricity and magnetism are treated, the greater part of the book is devoted to practical handling of machinery, details of construction, and computations such as will be encountered in every-day practice.

GAS ENGINES.—Modern Gas Engines and Producer Gas Plants. By R. E. Mathot. 8vo., 314 pages, 152 illustrations. $2.50

A practical treatise setting forth the principles of gas engines and producer design, the selection and installation of an engine, conditions of perfect operation, producer gas engines and their possibilities, the care of gas engines and producer gas plants, with a chapter on volatile hydrocarbon and oil engines.

GAS ENGINES.—Gas, Gasoline, and Oil Engines. Including Producer Gas Plants. By Gardner D. Hiscox. 8vo. 442 pages, 351 illustrations. $2.50

A complete book on the subject for gas engine owners, gas engineers, and intending purchasers of gas engines, treating fully on the construction, installation, operation and maintenance of gas, gasoline, kerosene, and crude petroleum engines, with special information on producer and suction gases.

GAS ENGINES.—Gas Engine Construction. By H. V. A. Parsell and A. J. Weed. 8vo., 304 pages, 145 illustrations. $2.50

A practical treatise describing the theory and principles of the action of gas engines of various types, and the design and construction of a half horse-power gas engine, with illustrations of the work in actual progress, together with the dimensioned working drawings giving clearly the sizes of the various details.

HEATING.—Practical Steam and Hot Water Heating and Ventilation. By Alfred G. King. 8vo. 402 pages, 304 illustrations. $3.00

An original and exhaustive treatise prepared for the use of all engaged in the business of steam, hot water heating and ventilation. The standard and latest book published. Describes all of the principal systems of steam, hot water, vacuum, vapor and vacuum vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation.

HYDRAULICS.—Hydraulic Engineering. By Gardner D. Hiscox. 8vo.; 315 pages, 305 illustrations. $4.00

A practical work treating on the properties, power, and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits, the horse-power of falling water, turbine and impact water wheels; wave motors, centrifugal, reciprocating, and air-lift pumps, etc.

INDUCTION COILS.—The Design and Construction of Induction Coils. By A. Frederick Collins. 8vo., 295 pages, 160 illustrations. $3.00

This work gives in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a ½-inch spark to a large one giving 12-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the descriptions are written in language easily comprehended.

LATHES.—Modern American Lathe Practice. By Oscar E. Perrigo. 8vo., 424 pages, 314 illustrations. $2.50

A new book describing and illustrating the very latest practice in lathe and boring mill operations, as well as the construction of and latest developments in the manufacture of these important classes of machine tools.

MAGIC.—Magic, Stage Illusions, and Scientific Diversions. Including Trick Photography. Compiled and edited by Albert A. Hopkins. 8vo., 556 pages, 420 illustrations. $[illegible]

This very interesting volume is acknowledged to be the standard work on magic. It appeals to the professional and amateur alike. The illusions are all explained in detail, showing exactly how the tricks are performed.

MECHANICAL MOVEMENTS.—Mechanical Movements, Powers, and Devices. By Gardner D. Hiscox. 8vo., 402 pages, 1,300 illustrations. $[illegible]

This is a collection of different mechanical motions and appliances, accompanied by appropriate text, making it a book of great value to the inventor, the draftsman, and to all readers with mechanical tastes.

MECHANICAL APPLIANCES.—Mechanical Appliances, Mechanical Movements, and Novelties of Construction. By Gardner D. Hiscox. 8vo.; 396 pages, 970 illustrations. $[illegible]

This book, while complete in itself, is in fact a continuation of the author's "Mechanical Movements, Powers, and Devices." The author presents to the reader information regarding nearly all conceivable devices for producing motion or accomplishing mechanical results.

SPECIAL OFFER: These two volumes sell for $6 each but when they are ordered at one time from us we send them prepaid to any address in the world on receipt of $[illegible].

PATENTS.—Practical Pointers for Patentees. By F. A. Cresee. 12mo., 144 pages. $1.00

Containing valuable information and advice on the sale of patents and elucidation of the best methods employed by the most successful inventors in handling their inventions. It gives exactly that information and advice about handling patents that should be possessed by every inventor who would achieve success.

PHYSICS.—Experimental Science. Elementary, Practical, and Experimental Physics. By George M. Hopkins. In two volumes. 8vo. 1,105 pages, 918 illustrations. Cloth, $5.00. Half morocco, $7.00

This book treats on the various topics of physics in a popular way and describes with rare clearness and in detail the apparatus used and explains the experiments in full so that teachers, students, and others interested in physics may readily make the apparatus without great expense and perform the experiments without difficulty.

PLUMBING.—Modern Plumbing Illustrated. By R. M. Starbuck. 392 pages, 10½ x 7¼, 55 full-page engravings. $4.00

A comprehensive and up-to-date work illustrating and describing the drainage and ventilation of dwellings, apartments, and public buildings, etc. The very latest and most approved method in all branches of sanitary installation are given.

PUNCHES.—Punches, Dies, and Tools for Manufacturing in Presses. By Joseph V. Woodworth. 8vo. 483 pages, 702 illustrations. $4.00

This work is a companion volume to the author's other work entitled "Dies, Their Construction and Use." It might well be termed an encyclopedia on die making, punch making, die sinking, and sheet metal working.

RECEIPTS.—The Scientific American Cyclopedia of Receipts, Notes and Queries. Edited by Albert A. Hopkins. Containing 15,000 selected formulas. 8vo., 734 pages. Cloth, $5.00. Sheep, $6.00. Half morocco, $6.50

Over 15,000 selected receipts are here collected, nearly every branch of the useful arts being represented. The alphabetical arrangement with abundant cross references makes it an easy work to consult. It has been used with equal success by chemists, technologists and those unfamiliar with the arts, and is a book which is useful in the laboratory, factory or home.

REFERENCE BOOK.—Scientific American Reference Book. Compiled by Albert A. Hopkins and A. Russell Bond. Containing 50,000 facts. 12mo., 516 pages, illustrated. $1.50

This book deals with matters of interest to everybody. It contains 50,000 facts, and is much more complete and more exhaustive than anything of the kind which has ever been attempted. It is indispensable to every family and business man. It is a book for every-day reference—more useful than an encyclopedia, because you will find what you want in an instant in a more condensed form.

STEAM ENGINES.—Modern Steam Engineering in Theory and Practice. By Gardner D. Hiscox. 8vo., 487 pages, 405 illustrations. $3.00

This is a complete and practical work issued for stationary engineers and firemen dealing with the care and management of boilers, engines, pumps, superheated steam, refrigerating machinery, dynamos, motors, elevators, air compressors, and all other branches with which the modern engineer must be familiar.

TELEPHONES.—Telephone Construction, Installation, Wiring, Operation, and Maintenance. By W. H. Radcliffe and H. C. Cushing, Jr. 16mo., 171 pages, 125 illustrations. $1.00

A practical book intended for electricians, wiremen, engineers, contractors, architects, and others interested in the installation of telephone exchanges in accordance with standard practice. Intricate mathematics are avoided, and all apparatus, circuits, and systems are thoroughly described. Selected wiring tables, which are very helpful, are also included.

TOOLS.—American Tool Making and Interchangeable Manufacturing. By Joseph V. Woodworth. 8vo., 544 pages; 601 illustrations. $4.00

A complete practical treatise containing a valuable collection of drawings and descriptions of devices, the results of the author's own experience.

TOOLS.—Modern Machine Shop Tools. By W. H. Vandervoort. 8vo.; 552 pages; 673 illustrations. $4.00

A new and fully illustrated work describing in every detail the construction, operation, and manipulation of both hand and machine tools, being a work of practical instruction in all classes of machine shop practice.

WIRING.—Electric Wiring, Diagrams and Switchboards. By Newton Harrison. 12mo.; 272 pages, 105 illustrations. $1.50

This work is a thoroughly practical treatise on electric wiring in all its branches, beginning with the simple circuit and working up to the practical every-day problems, all being presented in a simple and intelligent manner. It is in every respect a handy, well written, instructive, comprehensive volume on wiring for the wireman, foreman, contractor, or electrician.

Any of the above books will be sent postpaid on receipt of price.

Our complete catalogue of scientific and technical books sent free on application.

MUNN & COMPANY, - Publishers, - 361 Broadway, New York City

(Concluded from page 170)

ing a run of twenty-four hours, when handling material at the speeds as specified in the contract, no part of the motor will rise in temperature more than 70 deg. C. above the surrounding air All electrical equipment is designed for a direct current of 220 volts. The grab bucket has a cubical capacity of 100 cubic feet of limestone, and the scoop bucket of 132 cubic feet. Both buckets are especially designed for working in limestone. The grab bucket has an over-all width of about 7 feet 6 inches and an over-all length when open of 17 feet 6 inches. The capacity of the machine is 200 tons per hour The hoisting speed is 250 to 275 feet per minute, the racking speed 900 feet per minute and the whole bridge travels at the rate of 100 to 150 feet per minute

* * *

MEASURING A RIVER'S FLOW.

(Concluded from page 160)

the velocity recorded at a number of different depths in each strip By the vertical integration method the meter is moved at a slow uniform speed from the surface of the stream to the bottom and back again

For convenience of reference and comparison the results obtained are plotted in the form of a curve on a chart.

Another illustration shows the Great Falls of the Missouri River in Montana A gaging station at the point from which the photograph is taken was established by the Geological Survey in July 1902

The river is favorable at this point for water power development and shows the kind of stream apart from navigable rivers, measured and reported upon by the Survey In this way the Survey constantly brings to the attention of the investing and developing public many previously unnoticed but valuable water-power sites

We are indebted to the director of the U S Geological Survey for the use of the accompanying illustrations.

THE AVIATION MEETING AT RHEIMS

(Concluded from page 170)

with their Bleriot monoplanes Both Bleriot and Curtiss tried to lower their speed records for one circuit of the course, and the latter succeeded in making 2 seconds better time than before His time of 8 09 1/5 corresponds to almost 45 7 miles an hour Bleriot made the circuit in 8 08 2/5, which was 4 seconds slower than formerly

At the end of 2 hours, 22 minutes, and 51 seconds, Farman had flown 140 kilometers (86 99 miles) and beaten Paulhan's record. It was getting dark rapidly and the spectators could only see the machine as it passed before the grand stand Ten minutes and 19 seconds later he completed his fifteenth round, and less than five minutes later he had beaten Latham's record. One hundred and sixty kilometers (99 4 miles) were covered in 2 43 35 2/5, and 180 kilometers (111 88 miles) in 3 hours, 4 minutes, 55 2/5 seconds. As it was now 7 30, the nineteenth round afterward made by Farman was not counted in the official figures. He actually covered over 190 kilometers (118.06 miles) and remained in the air all told about 3¼ hours. As he finished in front of the grand stand a searchlight was thrown upon him He was pulled from his machine and carried upon the shoulders of his friends, receiving a decided ovation Thus, for the second time, he has won a $10,000 cash prize, the first instance being when he flew 1 kilometer in a closed circuit on January 13th, 1908 It is possible that he will try again to win this sum by making the 140-mile flight from New York to Albany In the flight for the Grand Prix, he carried enough fuel to fly 3½ hours.

The other prizes awarded in the Grand Prix de la Champagne distance race were as follows

Second, $5,000, won by Hubert Latham on his Antoinette monoplane. Distance, 154.5 kilometers (96 miles)

Third, $2,000 won by M Paulhan with his Voisin biplane. Distance, 131 kilometers (81 4 miles)

Fourth, $1,000, won by Count de Lambert with his Wright biplane Distance 116 kilometers (72 1 miles)

Fifth $1 000, won by Paul M Tissandier Distance, 111 kilometers (68 97 miles)

Sixth, $1,000, won by M Roger Sommer with a Farman biplane Distance, 60 kilometers (37 3 miles)

The distances covered by the other competitors were 50 kilometers (31 1 miles) by M Delagrange with a Bleriot monoplane, 40 kilometers (24 9 miles) covered by M Bleriot with one of his monoplanes, 30 kilometers (18 64 miles) covered by Mr Curtiss with his biplane, and 21 kilometers (13 04 miles) covered by M Lefebvre with his Wright machine

This first aviation meeting has demonstrated beyond a doubt that the real flying machine is here That aeroplane races will soon supersede the dangerous automobile races there can be no question We expect in our next issue to give full details of the successful machines at Rheims and their motors as well as further particulars of the flights which were accomplished

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co. 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., 361 Broadway, New York.

A Promise to Pay

WOULD you accept a stranger's note? No. Then why accept from a stranger any other promise to pay? A Fire insurance policy is such a promise. Ought you to accept it without knowing all about the Company? Your usual business confidence is based on knowledge. Why make an exception in that part of your business which deals with insurance? A name is worth nothing on any kind of a promise to pay unless it is backed by character and resources.

The Hartford Fire Insurance Company favors insurance knowledge, particularly about itself. Its promise to pay has never gone to protest. Its obligations to its policy holders are backed with such a good reputation and such ample financial resources that the more you know about it the more you will want protection by its policies.

It has published a book "Fire Prevention and Fire Insurance," which contains in separate chapters valuable information for Householders, Merchants and Manufacturers. It ought to be in the hands of every property owner in America. It may save you thousands of dollars, no matter in what company you are insured. It is free. Send for it.

DR. COOK AND THE NORTH POLE.

To set a question mark however small against the message from Dr Cook announcing that he had reached the North Pole would be to betray a spirit of ungenerous and captious criticism The conditions of complete isolation which must necessarily surround the man who launches himself with two native helpers into that uncharted sea of eternal silence and frozen desolation are such that the waiting world to which he returns—if he ever return—must needs accept his story of a successful quest without expectation of absolute verification or disproval For the theoretical point which we call the North Pole lies as was generally supposed and as Dr Cook has now proved in a vast field of eternally drifting ice Any monument set up by the explorer at the exact axis of the earth in attestation of his crowning triumph, would be carried steadily down over the dome of the world, to be ultimately lost in the more southerly seas, or cast up, with other flotsam and jetsam, on the northerly coasts

In the interests of scientific accuracy there will of course, be a subsequent verification as far as it is practicable of the distances covered and of the observations of the sun as taken during this wonderful journey, but this investigation will not be made because of any doubt as to the actual presence of Dr Cook on the twenty first of April nineteen hundred and eight at the North Pole

The man who can look Death full in the face throughout all the cruel sufferings of a two years' search for the secret of the frozen North is built upon lines too noble to admit of the slightest subterfuge or misrepresentation, and there are certain features of Dr Cook's expedition notably the total absence of ostentation in the manner of his setting out which should at least have sealed the lips of those who have received the news of his success with outspoken incredulity

Most of the great achievements of science whether in the way of invention or discovery may be regarded as the total result of the separate efforts of individual men To some one among the many it has been reserved to win the coveted goal and have his name written forever above its portals, and he above all others realizes and is only too glad to acknowledge how greatly his success is due to the unrewarded labors of his predecessors Each unsuccessful seeker for the North Pole gathered his quota of valuable experience and the facts as thus recorded have been of priceless value to those who came after Dr Cook himself an Arctic explorer of no little experience, will be the first to acknowledge his indebtedness to that splendid band of men, beginning with Sir John Willoughby in 1553 and ending with Peary, who blazed the way for his own magnificent success.

THE TRANSATLANTIC RECORD

It has been stated and with much truth that the degree of perfection of a country's transportation facilities may be taken as a fair measure of its industrial and commercial development and from the very first it has been realized that the value of any system of transportation is dependent very largely, and in some cases primarily upon its speed Hence there has been a constant effort to obtain the highest possible speed compatible with consideration of safety and reasonable economy Because of the old-time dangers and the, to many people present-day inconveniences and discomfort of ocean travel, the attainment of high speed has been nowhere so eagerly striven after as on the great oceans which divide continent from continent, and particularly on that three-thousand-mile stretch of water which lies between the old world and the new

The contest for what has popularly come to be known as the "Blue Ribbon" of the Atlantic has always possessed a certain fascination for the public, both for those who frequently make the crossing and those who never go at all The interest dates from the days in the early forties of the last century, when the "fliers" of that time were fighting it out between themselves at a speed of ten knots, down to the present day of turbine-driven liners that can reel off their 650 knots a day at speeds of twenty-five to twenty-six knots.

When the first line of steamships to cross the Atlantic on a regular schedule of sailing was established, now some seventy years ago, it took about fourteen days to make the trip from Liverpool to Boston. The first vessel to cross in less than ten days was an American boat, the "Pacific" of the famous Collins Line which performed the feat in May, 1851 It took another twelve years to reduce the passage below nine days, the "Scotia" making the passage in eight days and three hours, in 1863 To the Inman, now the American Line, is due the credit of bringing the passage below eight days, a feat accomplished in 1869 by the "City of Brussels," in seven days, twenty-two hours, three minutes. The seven-day limit was first passed by the "Alaska" of the Guion Line, which made the trip in 1882, in six days, twenty two hours, and seven years later, in 1889 the "City of Paris" of the Inman Line now the "Paris" of the American Line, brought the record below six days, by making the crossing in five days, nineteen hours and eighteen minutes.

It was not until the advent of the steam turbine that the record was brought below five days, the "Lusitania" accomplishing this feat in 1907 by crossing to the westward in four days, nineteen hours and fifty-two minutes. In the two years that have intervened since then, changes have been made in the propellers of both boats, which have considerably increased the speed, and on her last trip, concluded on September 2nd the last named vessel, crossing at an average speed of 25 85 knots, covered the Atlantic course in four days, eleven hours, and forty-two minutes thus bringing the record for the first time below four days and a half

The question has been raised as to whether this high speed is not gained at too great a cost. For it is a fact that both the "Lusitania" and "Mauretania" burn on an average about one thousand tons of coal per day The answer is that although the aggregate consumption is large the amount of coal burned in proportion to the size of the vessel is no larger and indeed not as large as that burned by the other fast Atlantic liners of less total displacement. Thus the "Deutschland," of 23 500 tons displacement, when steaming 23 5 knots, burns about 570 tons per day which is over one-half the consumption of the "Lusitania," whose displacement is nearly double that of the "Deutschland," and whose sustained sea speed is about two and a half knots greater Moreover, there is a large and ever increasing number of people who, either for business reasons or because of a dislike of ocean traveling, are perfectly willing to pay the higher rates which are necessary to make these high-speed vessels pay Furthermore, the advantage in the acceleration of mail service alone, is probably in itself sufficient justification for cutting down the time of transit between New York and London by twenty hours, as compared with other routes. For the adoption of Fishguard, on the west coast of Wales, as a port of call, and the installation of a service of fast steamer trains between that port and London, made it possible for the mails and passengers, on the last trip of the "Mauretania," to leave New York at 10 A M on Wednesday and reach London at twenty minutes past 7 on the following Wednesday evening

As to the possibilities of the future, it can safely be predicted that the question of bringing the transatlantic record below four days, is one of finding some new form of motive power It will never be accomplished by the turbine-driven ship. Whether the producer-gas engine can be developed to a point of compactness and efficiency that will enable it to perform the feat, is a question which the future must decide

ECONOMIC LOSS OF OVERCROWDING.

That the present overcrowding in the congested and poorer districts of our cities is to be condemned on humanitarian grounds goes without saying. The suffering which results therefrom, the multiplied miseries, not merely of the poor, but of a considerable section of the artisan class, of the tenement districts forms one of the most tragical phases of modern city life All of us who have given any thought to the matter, are convinced of this; but it is reserved for the social economist to show that the discomfort, suffering, and death directly resultant from overcrowding represent also a great annual monetary loss.

The method of stating the evil results of disease and accidents in dollars and cents has come into vogue of late years, and although the practice has been made the subject of some criticism and ridicule we consider it is justified on sound economic grounds A recent analysis of this character is the statement issued by the Committee on the Congestion of Population, which estimates that the annual economic waste in this city from certain preventable diseases has reached the high figure of between [illegible] and $41,000,000. This estimate is based on the loss of time of the wage earners through illness and death, which are traceable largely to congestion of population. The Health Department has made the following classification of preventable diseases: Typhoid fever, pneumonia, broncho-pneumonia, diphtheria, smallpox, cerebro-spinal meningitis, diphtheria and croup, measles, scarlet fever, whooping cough, diarrheal diseases, tuberculosis pulmonalis. The committee argues that if the above diseases are preventable, and the economic waste of the community in the way of loss of wages, etc., amounts to $40,000,000 a year, it would be the part of wisdom to make a more careful study of the predisposing conditions, and particularly of means to prevent overcrowding

In arriving at the above estimate, it is considered that the prospective earnings when death occurs between the ages of 20 and 62 have an average value of $2,000 for men and of $1,000 for women For the four years from 1905 to 1908, it is estimated on the above basis that the waste from death, due to certain preventable diseases in New York, may be conservatively estimated at over $95,000,000, and that the economic waste from sickness due to these same diseases may be placed at over $71 000,000, making a total economic loss of over $166,000,000.

THE ELIMINATION OF GRADE CROSSINGS.

Although the advent of the automobile has attracted public attention in a most tragical manner to the peril of railroad grade crossings, the loss of life among the users of automobiles represents only a certain proportion of the annual number of fatalities due to this cause. The time will come when our increasing regard for the sanctity of human life will lead, either to a total abolition of crossings at grades, or to such an ample protection as will place the responsibility for accidents of this character almost entirely upon the highway traffic, whether pedestrian or vehicular

There are at the present time in New York 10,544 points at which railroad tracks encounter public highways, and at 1,698 of these points the crossings at grade have been removed The protected crossings number altogether 3 676, distributed among the different railroads according to the following percentages Long Island Railroad, 51, New York Central, 43, Delaware, Lackawanna & Western, 42, Erie, 31, Delaware & Hudson, 30, New York, Ontario & Western, 30, Lehigh Valley, 20

During the last five years the different railroads, with the assistance of the State and municipalities, have been actively engaged in reducing the number of grade crossings on their lines by either elevating or depressing the tracks. These grade crossings have been reduced in certain percentages of the total from 22 on the Long Island Railroad down to 10 on the Delaware & Hudson Railroad

The work outlined by the Long Island Railroad Company includes the removal of 14 grade crossings on the line to Manhattan Beach, 45 grade crossings on the Bay Ridge line, the elimination of some very dangerous crossings on 14 streets by the construction of a tunnel under East New York Hill, and the removal of some 203 grade crossings in Queensboro During the last Legislature a bill authorizing the city to share the expense of removing these last-named crossings failed of passage, indeed, for the first time in many years, the Legislature at its last session failed to make any appropriation for continuing the work of grade crossing removal in this State. Up to the present time the Long Island Railroad has spent $12 500,000 in improvements involving grade-crossing elimination, while the city's share in the improvements involved the expenditure of $3,750,000 The company is prepared to spend an additional $6,000,000 in getting rid of the 203 crossings at grade which still remain in Queensboro, provided the city would continue its former policy of contributing one-half of the expense.

In view of the fact that grade-crossing removal not merely eliminates a most serious menace to public safety, but that the elevation of the tracks results in a quickening and all-round improvement of the train service, it would seem that there are very good reasons why the Legislature should enable the city to continue its former policy of contributing to a work which may be justly considered as a public improvement. The city, of course, should never have allowed the tracks to be laid through the streets at grade in the first instance. On the other hand, a large proportion of the mileage, now lying within city limits, was surrounded by open country when the road was first laid.

ENGINEERING.

What is claimed to be the record torpedo shot of our navy was made during the recent maneuvers of the Atlantic fleet off Provincetown, when the submarine "Cuttlefish," selecting the battleship "Vermont" for attack, fired a torpedo at a range of 3,800 yards, hitting the "Vermont" squarely amidship.

A gas-driven street car is now under construction in Philadelphia, which is to be tested on the line of the Metropolitan Street Railway Company of New York in competition with the electric cars of the company It will be driven by two 4-cylinder motors, each of 24 horse-power These will be water-cooled, and piping will be led from the motor jackets around the interior of the car to heat the latter during winter service.

The fast steam yacht "Winchester," which is now being built by Yarrow will attract considerable attention because of the up-to-date character of her motive power Steam will be supplied by water-tube boilers fired exclusively with oil fuel, and the yacht will be driven by Parsons turbines of 2 400 horse-power operating three single-propeller shafts. The vessel, which is of 180 tons, is 165 feet long, 15 feet 6 inches beam and 9 feet 9 inches deep

The French battleship 'Iena," which a few years ago was wrecked by an explosion of the smokeless powder in her magazines is being used as a target and several important problems are to be determined relating to the effect of shell fire. Recently after caged animals had been placed on board the ship, she was attacked by the cruiser "Latouche Trouville" with high-explosive shells. The deadly effect of the gases of the explosion was shown by the asphyxiation of several of the animals.

There is no doubt that one cause of the objection to motor cars on the part of a certain section of the public is the use of headlights of dazzling brilliancy The Technical Committee of the Royal Automobile Club are making experiments with a view to finding a lantern which will give sufficient light for vision, but will at the same time be so controlled as not to dazzle the drivers of approaching vehicles or pedestrians. The tests are being made with acetylene petroleum and electric lamps.

Last week we made note of the retirement of two famous record holders, the "Umbria' and 'Etruria,' from the Atlantic service. It is now announced that the "Lucania," which was recently burned at her pier in Liverpool will not be repaired, but will go into the hands of the underwriters She was the first vessel to make the transatlantic trip at over 22 knots an hour Her place will be taken by a new turbine 21 knot ship of 25,000 tons.

The work of installing the roadbed rails, and operating equipment of the recently completed D tube of the Pennsylvania tunnels below the East River, was begun in Long Island City last week Of the four tubes, the two inner tubes, known as B and C, are nearing completion and all four can be finished and in readiness for operation between Long Island City and the Pennsylvania Terminal on Manhattan Island by the first of next year.

The Cleveland Industrial Exposition, which we recently had the pleasure of visiting has been successful beyond the expectation of the Chamber of Commerce, which is responsible for its promotion The exhibits were more numerous and of a higher character than was anticipated, and the attendance has run up to as high as 30 000 daily It looks as though the huge national exposition, which as in the case of the St. Louis Fair had grown to an altogether unwieldy size, will in the future be replaced by local expositions held in the larger cities.

Everyone who is familiar with the valuable historical collection of scientific appliances now at South Kensington, London, will regret to learn that "at present these treasures are huddled together in makeshift buildings quite unsuitable for the purpose of a museum" The commissioners of the great exhibition of 1851 offered $500,000 and a suitable site for a properly equipped science museum provided the government would undertake to maintain it. A delegation representing all the scientific interests in Great Britain have urged the government to give their immediate attention to the proper housing of this collection.

The grand total of excavation on the Panama Canal during the month of July was 2,842,260 cubic yards, which is 53,533 cubic yards less than the total for June, and 1,037,077 less than the highest record, made during the dry season in March of the present year Of the amount removed from the canal prism, 1,684,663 yards were taken out by steam shovels, and 1 107,814 yards by dredges. The mean rainfall was 10.66 inches for the month, in which there were twenty-six working days. Incidentally it may be mentioned that the Tariff Act, approved by the President August 5th, authorizes a bond issue of $290,569,000, in addition to the $84,[illegible] heretofore issued for canal construction.

ELECTRICITY.

During the recent rioting at Barcelona, all the gas and electric-light plants were out of commission, and the city was illuminated only by the searchlights of warships in the harbor

At the annual convention of the Association of Edison Illuminating Companies, the licensees under Mr Edison's patents, held last week at Scarborough on the Hudson, was celebrated the thirtieth birthday of the incandescent lamp

In order to compete more effectively with the gas company which lets kitchen and other stoves the municipal electric light plant of Aberdeen, Scotland has laid in a stock of electric heating and cooking apparatus, which it proposes to offer for hire at proportionately low rates

An electrical exhibition will be held in Boston from the 15th to the 25th of November at which all the latest labor-saving and comfort-giving devices will be exhibited, with elaborate and novel decorating and lighting effects. Prizes will be awarded for the inventions and ideas of amateurs, and space set aside for the exhibits of amateur wireless operators

Our allusion last week to a power shovel as an unlikely machine to be successfully electrically driven has caused our attention to be drawn to an electric well-drilling machine produced by the Keystone Driller Company of Beaver Falls Pa and successfully operated near Chicago From the very wide range of its operations, often remote from habitation let alone power plants, the driller certainly seems an even less likely machine to be operated electrically than the shovel, but the supply has doubtless been created by a demand and in districts where prospecting or other drilling is carried on within reach of electric wires, the machine should have great advantages.

The Montreal Light Heat and Power Company has announced that it will engage in the ice business obtaining water from artesian wells and freezing it by electric power into blocks of any desired shape and size so as to avoid cutting This is an example which might with advantage be followed by many a smaller plant. Every lighting plant must be capable of carrying a certain maximum load at the time of night when most lights are in use but for at least 18 hours out of the 24 the load is from half as much in large cities to almost nothing in small country places where there is little industrial use of electrical power so that during the greater part of the day much of the capital invested is earning no dividends The surplus power might just as well be used in making ice and providing another source of revenue, particularly as the time when the peak load is of shortest duration coincides naturally with that of the largest consumption of ice.

Remarkable results have been obtained by an electrical ozone-generating apparatus recently installed at the public library on Michigan Avenue and Washington Street, Chicago It appears that complaints had constantly been made of the unpleasant odor from accumulated human emanations and this in spite of an excellent purified-air ventilation system the nuisance becoming such that an attempt had to be made to counteract it. Direct current at 110 volts is converted to alternating at 120 by a rotary converter and the latter stepped up to 8 000 volts by a transformer This high tension secondary current discharges between the plates of the ozonizer through which is drawn the air led to the ventilating apparatus above Enough oxygen is converted to free ozone to kill any living organisms in the air and neutralize any kind of odor The most remarkable result of the installation appears to be the substitution for unpleasant if not actively unwholesome air of an atmosphere actively healthful

The Electrical Review suggests that trackless trolleys," such as are successfully used in Austria and elsewhere in Europe that is to say, electric vehicles running on ordinary roads, but taking power from overhead wires might be advantageously used to take the place of horse-drawn stage coaches which still connect with the railroads numerous villages having no other means of transportation even in the most populous parts of the country It is pointed out that such stage lines rarely have a traffic which would encourage the projection of electric railroads to take their place as a profitable venture but figures are quoted to show that of the cost of roadbed track, and electric-line construction in electric railroads, only 15 per cent or less is for overhead conductors and poles, considering therefore that electric road vehicles are obtainable for a much lower cost than railway cars, and that the power-generating plant would be so much less for a little line operating only three or four stages back and forth per day, it is obvious that such a trackless trolley system could be undertaken for a tenth of the cost of an electric railway, and with a much better chance of profitable operation.

SCIENCE.

Plans have been filed for a new home for the American Geographical Society at 156th Street and Broadway The building will form one of a group that now includes the Hispaño Society's home and the Numismatic Museum although it has no connection with either institution The building will be erected from funds provided by Mrs C P Huntington The estimated cost of the building will be between $250 000 and $300 000

Prof. Charles Richet of Paris has devised a means for purifying the air in rooms According to press dispatches, his apparatus is an air filter which mechanically sterilizes air Very fine drops of glycerine are scattered along the walls of a cylinder containing a suction fan Each particle of air drawn in by the fan is freighted with glycerine and hence tends to drop thereby carrying with it the germs dust and microbes with which it may be laden

The peculiar odor of clay is unquestionably due to organic ingredients Although these cannot be isolated or detected by chemical analysis they can be classified according to their physiological effects which vary widely Rohland has succeeded in transferring the odors of clay to saccharate of iron and has thus recognized ten distinct varieties Louis has made similar observations employing ammonia as a vehicle for the odors

Charles S. Philipp has produced a variety of glass which is a good conductor of electricity by fusing together 32 parts of sodium silicate, 5 parts of borax 0 8 part of lead oxide and 0 2 part of sodium antimoniate The glass is not attacked by acids Its electrical resistance is about 1 000 times smaller than that of ordinary glass It is used chiefly for the disks of electrometers and electroscopes Filaments of the new glass may even be substituted for the gold leaves of an electroscope

A human hair of average thickness can support a load of 6¼ ounces and the average number of hairs on the head is about 10 000 A woman's long hair has a total tensile strength of more than five tons and this strength can be increased one-third by twisting the hair The ancients made practical use of the strength of human hair The cords of the Roman catapults were made of the hair of slaves and it is recorded that the free women of Carthage offered their luxuriant tresses for the same use when their city was besieged by the Romans.

In the early part of the present year the French Academy of Sciences discussed a communication in which it was asserted that the human body emits radiations which affect photographic plates In the course of the discussion De Fontenay demonstrated that the effects which had been attributed to radiations could be explained perfectly by the warmth and moisture of the body Later an attempt was made to sustain the theory of human radiations by the statement that the Lumière company had been compelled to discharge several employees who fogged the plates that passed through their hands De Fontenay investigated the matter and found that nothing of the kind had ever occurred at the Lumière factory Every case of fog was due to accident and to well known causes—finger marks packing strips lantern fog etc not to any mysterious human radiation In regard to animal magnetism unknown natural forces and other occult agencies it is bad enough to be assailed with crude experiments and unproved assumptions without the aid of false testimony Legends of this sort are easily propagated and hard to kill Ten years hence the alleged experience of the Lyons plate makers will doubtless be still adduced as a proof of human radioactivity

A. Kuerth has obtained the following results in a series of experiments on the effect of heating on the hardness of various metals A bar of very uniform copper was cut into five pieces 2½ inches long and 8/10 inch broad In the cold all pieces showed exactly the same hardness. They were heated in oil or saltpeter baths to temperatures of 300 570 660 700 and 840 deg F respectively for from one to thirty minutes and allowed to cool the hardness in each case being determined at the temperature of about 70 deg F The specimen heated to 300 deg F showed a hardness which was almost independent of the duration of heating, the coefficient of resistance being eighty kilogrammes per square millimeter but in other cases very great variations were observed With the bar heated to 840 deg F the value of the coefficient fell in one minute to 40 and thereafter remained almost constant at 37 Other experiments were made with specimens of nearly pure nickel aluminium zinc and tin, and with various Krupp steels The temperatures used ranged from —116 deg F to 900 deg F In general the hardness of steel decreased as the temperature rose up to about 100 deg. F at which point there was a slight increase in hardness, which was followed by a diminution as the temperature was raised still higher

COUNTING OUR PEOPLE BY MACHINE.

BY H. HAMILTON TALBOT

The counting at the end of each decade of every man, woman and child in the United States is one of the biggest undertakings the government is called upon to assume To facilitate counting, machines will be used invented by Mr James Powers, a mechanical expert of the Census Bureau, for use in the thirteenth census which were successfully tried in the recent Cuban census, and now in use in the Division of Vital Statistics of the Census Office.

The mechanical method for counting the census requires two types of machines, which are of equal importance, and each essential to the successful use of the other The keynote of the system, however, is a punched card which contains the data collected by the enumerators who travel from house to house in every nook and corner of the land The data include the nature and extent of our industries the amount of our wealth etc By means of the punched card a tabulating machine mechanically classifies the data thus sent in to the Census Office by the enumerators The location of the holes on the cards means everything to the tabulating machine as will be seen later, for the special position of a hole within the limits of certain boundary lines on the cards means one thing and in another position another thing It is this location of a punched hole on a card that enables the tabulating machine to transfer the value of that particular position of a hole on a card to a number of counters, which classify the data and obtain totals

One of the punched cards.

The punching machine which was used in the eleventh census, and again with improvements at the twelfth census, was a rather simple affair, in which the pressure of a lever by hand was necessary for the punching of each and every individual hole The machine recently invented for punching bears no resemblance to the old apparatus and is run by electricity instead of hand power

The new machine is built on the plan of a typewriter with 240 keys. The operator instead of punching one hole at a time presses as many keys as may be necessary After all the facts have thus been recorded by the keys a bar resembling that of a space bar on a typewriter is pressed, which brings an electric motor into play whereupon all the holes are punched at once without any effort on the part of the operator The average number of cards punched per day at the Census Office with the hand puncher was 900 while with the new machine a speed of 4,000 cards per day is attained In the old punching machine a hole was punched in a card every time a key was depressed If an error was made the card had to be thrown away thus wasting not only the cards but the operator's time In the new machine each key is depressed independently of the others and can be released at will without punching a hole or recording a fact until the operator is ready to press the motor bar, which punches all the holes at once. Before the operator punches any holes the operator can look over the depressed keys and ascertain whether all are correct. If an error be discovered, the wrong key can be released and the error rectified before any punching is done The color of the keys for each field of the card is different, which enables the operator at a glance to locate the keys representing the different fields of information. The cards are fed to the machine from the back by electricity

To make this method clearer, study the accompanying picture of a card, which is now in use in the Vital Statistics Division of the Census Office and which is representative of all cards used in their new punching machine, a change in the symbol keys of the machine making it available for population work.

The holes are divided into two classes by the vertical lines on the left-hand side of the card The first class aided by the large numerals at the right hand edge, identifies the person, and enables the census expert to find immediately the original entry from which the card was made, the second class gives all the statistical information regarding the person for whom the card was made. For instance, the *W* means that this person was white, the *M* means that the person was a male, the *Dec* that he died in December, the 20 and 4 that he was 24 years old, the *Sg* that he was single, the *US* in the next three fields that he was born in the United States, as were both his parents. The two fields immediately below show his occupation at time of death and also the cause of death A similar card is being made in the Census Office for each death reported in the United States, and one will be punched for the many million inhabitants reported by the enumerators in the forthcoming census

In connection with the invention of this new machine, it is interesting to note that it will render it possible to announce the total population at the next decennial enumeration in record-breaking time; for automatic counters are attached to the keys, and register on a dial every time a hole is punched. Thus, just as soon as the 90,000,000 cards (more or less) representing the people of the country have been punched, the Census Office will be enabled to announce immediately the totals as to the different classes of our population—males, females, natives, foreigners, white, colored, married, and single. Under the old system, when all the punching was done by hand, these figures were not available until the tabulating work was started.

COUNTING OUR POPULATION BY MACHINE.

Photographs copyright 1909 by Waldon Fawcett.

After the transfer of information to the cards has been completed, the schedules from which the information is derived are filed among the government records, and all the work of statistical tabulation is done with these cards. One notices that the clerks working on them cannot tell the names or addresses of the individuals for whom the cards stand, and that thus in the presentation of census tables the personal element is entirely lost.

After the cards have been put through the punching machine, they are ready for the tabulating machines. The operator puts the cards, one at a time with her right hand, into a box with a multiplicity of little spring-seated pins above the card and a corresponding series of mercury cups below it. As she moves her hand from the machine to pick up another card she touches a spring on the lower edge of the pin box, which brings an electric motor into play The pins which are in line with the holes of the second class on the card descend through the holes, and by touching the mercury below make so many electric contacts. Each pin and its mercury cup are terminals of a separate current passing through an electro-magnet controlling a counter or dial Thus, referring again to the card, the current entering the field for *Col*, or *Color*, would have five possible paths. The routes diverge at the five points where holes in the cards might have been. Of these five routes four are closed by the surface of the card, and the current is compelled to go by the fifth, where the hole has been made, and is guided to the dial for *Color*, and so on in each field. These dials contain the various combinations of statistical information, from which the tables as finally set forth in the census volumes are made.

An automatic recording and printing system—on the plan of the familiar stock ticker—is connected with each dial. When the operator wishes to make a reading of the dials a button is pressed, with the left hand, and the figures on the dials are printed on the ticker paper, from which they can be read. The dials are automatically reset. In the machines used in former census work the dials had to be read and the results recorded by hand—a proceeding productive of many errors—and then all the dials had to be reset by hand, a time-consuming operation The daily output of the old machines averaged 18,000 cards, while the new machines are counting 28,000 cards per day.

An occultation of Mars occurred on September 1st, which was observed by many astronomers, although the event is not of much scientific importance.

HOW SUDD CHOKES THE NILE RIVER.

BY DAY ALLEN WILLEY.

The actual head of navigation of the Nile River is considered as at the town of Gondokoro, for the reason that the depth of water is sufficient to float a steamer to the famous city of Khartoum, a distance of 1,061 miles to the northward. South of Gondokoro are stretches of water available for light-draft boats, but the interruptions to navigation are so numerous that this portion is not considered a practical route for water traffic. When Mr Roosevelt concludes his African hunt at the banks of the Nile, his expedition will take a special steamer at Gondokoro and attempt to reach Khartoum by water The word "attempt" can be appropriately used, for the reason that the channel may be blocked by sudd in the river to such an extent that the party must go overland for some distance if they would reach Khartoum at the date expected

Just how the word "sudd" originated is a mystery but every Egyptian traveler knows perhaps too well what it is, for many a time this vegetation has choked the upper Nile to such an extent that boats have been held weeks at a time until a way could be cut, burned, and pulled through it So dense, so thick, is the water growth, that if allowed to continue, it forms a literal mat over the channel, so compact and so strong that such animals as the elephant, even the hippopotamus, have been seen to go across it, and without breaking through the matted roots, branches, and leaves In short, the rapidity with which the sudd spreads over the water, and its parts interlace, is such that in a few weeks a space of the Nile once clear of it will be completely hidden by a mass of waving papyrus but underneath is a combination of water plants that attach themselves to the papyrus stalks, and form what is literally a cover of vegetation, through which not a foot of the river may be visible

In all of the thousand and odd miles from Gondokoro to Khartoum, and even above Gondokoro, does this water growth flourish, and consequently the engineers of the Egyptian government have no small task to keep open a channel for the steamer service. Although but one boat monthly plies regularly between the places mentioned, there is considerable tourist and other traffic near Khartoum, and a fleet of craft are in service to remove this curious growth. To clear a channel even large enough to admit the smaller type of vessel is not an easy task, since the sudd is so dense and so difficult to pull out—the usual way of getting rid of it. Where the Nile is wide and the water of sufficient depth, the vegetation is left untouched unless it entirely closes the channel, so a boat may make a detour of several miles out of the ordinary course, skirting one of the strange floating islands. In fact, the growth along the upper Nile is so enormous that patches of it skirting the shore may be seen for distances of a hundred miles without a break or gap to the land itself. Islands of the stuff a half dozen miles in area are sometimes carried down in the Nile flood current until they lodge against a projection of the shore or ground in shallow water Thus it is that new "islands" of it are created often far downstream from the region where the sudd is most abundant.

In clearing the river channel of sudd the engineers have devised several schemes. The top growth frequently becomes so dry that they can burn it over like so much grass. This removes much of the weight of the plants, but they are so matted together, that saws are actually used to separate the growth, as it cannot be removed in any other way The vessels employed for sudd clearing, while light-draft boats, are strongly built and have blunt bows so that they can be forced against the bank of vegetation They are provided with steel cables or hawsers saws, and axes, and carry crews of natives who are experts in working upon the sudd.

Section of upper Nile, showing channel nearly filled with sudd.

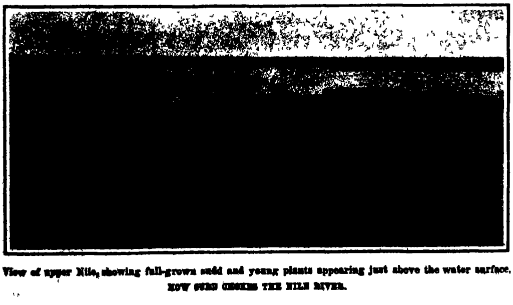
Detail view of water papyrus or sudd.

The way in which the channel is cleared is as follows Often the water is so completely hidden that the first difficulty when you are encountered by a barrier of sudd, is to discover where in this sudd the river bed runs. This is done by a method of "sounding" through the sudd The average depth of water in the sudd may be only a few feet, but when the true river bed is reached this suddenly increases to a depth of 15 to 18 or 20 feet. Having found the real river bed, the first thing to do is to cut down or burn the top growth *consisting mostly of papyrus.* A curious and unexplained fact noted by the engineers is that when papyrus is fired, the flame frequently spreads along what is afterward discovered to be the true bed of the river

Having cleared the top of the sudd "block ' the men are landed with large saws to cut along the true river bank, which may be either submerged with a few feet of water over it and papyrus and sudd on it, or solid ground with ant heaps the solid ground never being of any great extent and always surrounded by swamp Cross and parallel cuts with the saws are then made through the sudd dividing it into blocks of a convenient size for the steamer to tear out the size of these blocks of course depending on the consistency of the sudd and the power of the steamer

Having cut the sudd into convenient blocks the bow of the steamer is run into the block the loop of steel hawser both ends of which are made fast to the steamer, is passed over the bows of the steamer where it is taken by the men on board and placed in what is called the trench cut and held down with their feet. The steamer then goes full speed astern the men all standing on the hawser to keep it in position In the case of tough sudd as many as twenty trials may have to be made in this way before the block of sudd eventually tears away In the case of shallow light sudd the hawser may be trodden down too deep and slip underneath, in which case the block will be cut free but has to be again gripped by the hawser and towed away When the block is torn out the steamer goes slowly astern till the mass is pulled clear into the current—if there is one—when it is cast adrift to float downstream where it is gradually disintegrated If there is no current it is towed to a piece of open water where as a temporary measure it can be tied by ropes to the bank leaving a wide enough channel for the steamer and on the appearance of a current, be cut adrift to float down stream

The chief growths in the sudd are papyrus and tiger or elephant grass a kind of bamboo growing to a height of 20 feet or more To these climbs a creeper of a kind of convolvulus. Another portion of the sudd consists of ambatch and a long sword grass that cuts like a knife known as oom soof The steamer could cut its own way through this latter which in the presence of a current would be broken up and float downstream offering no obstruction In calm water, however it does not float away but ob-



View of upper Nile, showing full-grown sudd and young plants appearing just above the water surface.

HOW SUDD CHOKES THE NILE RIVER.

structs the steamer by constantly fouling the paddle-wheel There is another very light kind of duckweed which covers some of the small open pools, and in the absence of a current is a great nuisance for the same reason

Strange as it may seem, the sudd interferes but little with the flow of the river, and the Nile passes under it with little resistance This is because the growth is principally near or on the surface As the river is over a mile wide in some places, and the deep channel may be only a hundred feet, it is often hard to tell where to find the channel to clear it, as all of the water may be hidden Men with long poles push them through the sudd to the water and by this method of sounding locate the channel, when the sudd clearers get into operation

The water papyrus plant so often seen in the sudd has given rise to the theory that the growth is composed of papyrus but an analysis by naturalists shows that there are four vegetable elements that are the principal creations of this strange natural bridge They are known scientifically as the *Papyrus cyperus* the *Panicum pyramidale* the *Phragmites communis*, and the *Typha australis* They form the framework of the mass but interlaced with them as stated, are several species of twining and climbing plants that greatly strengthen this strange fabric It may as already stated support even the weight of an elephant where it is thick enough The papyrus with its wide top covers the sudd and thus gives the idea that it is the only obstacle when as a matter of fact this is a great water carpet woven as deftly and strongly as if by the loom

◆

The Highest Flight of a Balloon.

The unprecedented elevation of 95,250 feet or 18 miles was attained by an unmanned registering balloon which was recently released at the Belgian meteorological institute at Uccle At this elevation the barometric pressure is only 2/5 inch The greatest height ever attained by a manned balloon is about 6.7 miles or 35,400 feet The Berlin aeronauts Berson and Suering who established this record were unconscious when they reached the highest point of their flight

The Belgians adopted Hergesell's plan of attaching the instruments to a small and partially inflated balloon suspended from a larger and fully inflated one The large balloon rises until it bursts and the small balloon falls slowly so that it can be easily observed and brings the instruments safely to earth At the maximum elevation 18 miles the thermometer recorded a temperature of —82 deg F but a lower temperature -88½ deg F was registered at the comparatively small elevation of 8 miles These observations appear to support the hypothesis that some of the ultra red solar radiation is absorbed by the higher strata of the atmosphere but additional observations will be required to solve the question

The Current Supplement

What is probably the very highest branch of the molder's art is the casting of bronze figures and statues The opening article of the current SUPPLEMENT No 1758 discusses this art most thoroughly The ultramicroscope and ultramicroscopic objects are discussed in simple language Charles Engel tells something of the economy of cold in modern life Of the many problems that confront the American housewife the subject of vegetables for her table during the winter months is not the least important How that problem can be solved is told by J F Breazeale in an article entitled Canning Vegetables in the Home ' Prof F H Starling points out the lesson of evolution The importance of ferments in organic life is dwelt upon by Dr A Zart Sir Andrew Noble recently read a paper before the Institution of Engineers and Shipbuilders on the history of propellants That paper is reprinted in the current SUPPLEMENT The Aerial Propeller Its Form and Construction is the title of an article by Lucien Fournier Sir J J Thomson's brilliant paper on recent studies of electricity and matter is concluded

◆

An epidemic disease known as the white' of oak has been studied recently by Griffon and Maublanc It prevailed in France especially during 1908 The disease is properly called oidium and it is not confined to the oak but also attacks the ash elm and chestnut It is also found in Algeria The disease is supposed to be due to a micro organism known as *Microsphera alni* The question as to whether it is indigenous or not has not been determined It increased in France during 1907 and 1908 in an unusual way Should we suppose it to be imported like blackrot or mildew this would appear bad for the future while if it is indigenous it is likely to disappear again Some persons advocate a treatment with sulphur but others claim that this has no effect One important point in any case is the time of the year when the treatment is made

Correspondence.

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN:

If it is not too late, I would like to add a few words to the correspondence which appeared recently in the SCIENTIFIC AMERICAN concerning the number of our ancestors.

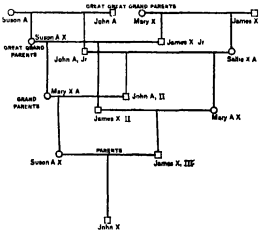
Your first correspondent, Mr A. K. Venning, comes to the conclusion that long before the 5,000 or 6,000 years of authentic history is reached, the number of our ancestors would be so large that there would not be standing room for them on the face of the earth, while your second correspondent, Mr Ernest McCullough is inclined to ridicule this, and thinks that the figuring is more apt to work the other way Permit me to offer the following explanation The explanation lies in the difference in the ages of our ancestors. There is usually a considerable divergence in the ages of our grandparents, and going back farther, the difference in age increases with each generation, so that by the time the fifth or sixth generation back is reached, some of our ancestors would be new born babes while others would be in their graves. It is readily understood from this that the number of our ancestors is just as liable to decrease with each generation owing to the ravages of the grim reaper Death as to increase If our grandparents were all born the same year, all married the same year, and both couples had children the same year Mr Venning's conclusions would be correct, provided no one ever died When I say grandparents in this case, I mean all our ancestors indiscriminately

East Canaan Conn DEWEY C CANFIELD

—

To the Editor of the SCIENTIFIC AMERICAN

I notice in one of your recent issues a communication from Mr Venning of Los Angeles, Cal in which he seeks a solution of the puzzling question of accounting for the discrepancy between the apparent



number of a man's ancestors as given by the rules of geometrical progression and the lesser number which experience shows to be the case I think the solution is to be found in the simple fact that our ancestors have been in the habit of intermarrying with their cousins sometimes this relationship being near and sometimes more distant. Otherwise we would inevitably enjoy our allotted number of 2^n ancestors for any given generation Thus one set of one's great grandparents on the maternal side are often one's great parents on the paternal side also For instance a man whose ancestors for two generations had intermarried with their first cousins would have the lamentable misfortune of possessing but four great grandparents as shown by the inclosed diagram, when by all the rights of arithmetic he should have sixteen to be proud of Of course this relationship is often so far removed that it is impossible to trace it, but each time one's parents have a common set of ancestors no matter how far removed, it is evident he is being deprived of his allotted share of ancestors to that extent at least, and it might be mentioned it would be next to impossible to find any two Englishmen to-day who had not in common an innumerable number of ancestors. F W A

Knoxville, Tenn

—

To the Editor of the SCIENTIFIC AMERICAN

Publication of this problem has not as yet brought any solution, but it has cleared the air to some extent, I am glad to see May I point out to Mr King that the question of relationship of descendants has not really anything whatever to do with the answer? He is leading the hunt off on a false scent. If we leave out of consideration altogether the present inhabitants of the earth, and start from the premise that there is only one person alive to-day—say Mr. Constable's John Brown—the problem remains unaltered, only being thrown back a few centuries.

The [illegible] [illegible] is: [illegible] generations [illegible] John Brown has 2^n ancestors, then it is only a question of time—of a few thousand years—for the number then alive to be so great that there would not be standing room for them upon the globe. The existence of 1,500 million or so of other persons, and those, moreover, composed of different races, to say nothing of the vast animal life, only adds to the mystery If we limit the inquiry so as to bring it more clearly within the focus of human understanding, say to 1,000 years, we find that one single Englishman alive to-day had, at the time of Alfred the Great, 1,094 millions of progenitors living at that time, as mentioned in my original letter

Five hundred years gives a proportionally similar result, as incomprehensible and puzzling.

Los Angeles, Cal. A. K. VENNING.

THE RECENT CURIOUS ECLIPSE OF THE SUN.

To the Editor of the SCIENTIFIC AMERICAN

The recent eclipse of the sun was both annular and total, an anomaly which becomes intelligible if we consider the data given in the American Ephemeris and Nautical Almanac for 1909, under the head of Eclipses and Phenomena Accompanying the Same." The interesting phenomenon was not caused *per se* by the varying distance of the moon, which could not be possible, but by the varying distances on the earth where the moon's shadow or better where the shadow caused by the moon reached the earth's surface. Let me say that the phenomenon is a rare one and can occur only when the sun, moon and earth are so situated that the moon's position with relation to the other two bodies gives it such an angular diameter that the nearest point of contact of its shadow on the earth will just cover the sun's disk, thus giving us a total eclipse This condition we might call a critical one, for should that distance be increased by a few hundred miles between the moon and the point of contact of its shadow on the earth, there would be an apparent decrease in the angular diameter of the moon's disk thus allowing an annulus of light from the sun to pass over its edge, and thus producing an annular eclipse

Now this is just what happened in the last eclipse. The first annular phase was about the latitude of Tomsk in Siberian Russia in the early morning, and as the solar rays had a large angle of inclination, they had to travel much farther before they reached the earth than when the sun was in the meridian at midday

The same conditions were present when the sun was low in the western horizon, i. e, the solar rays reached the earth's surface at a low inclination, thus repeating the annular phase on the west coast of Greenland in the evening.

Just at what points on the earth's surface the total phase commenced and ended, I am uncertain I do not believe that the points have been worked out, owing to the fact that the duration of the eclipse at any one place would be so short that astronomers did not deem it worth while to consider it as of enough value to send an expedition, even should it have been in an accessible part of the world As the total phase was likely all within the Arctic Circle it goes without saying it wasn't worth while Data are given in the American Ephemeris by which the problem can be solved for any part of the path of the eclipse

I made a search through Grant's "History of Astronomy" and found no similar eclipse noted, but Dr Schlesinger, director of our observatory at Allegheny, tells me that it may occur once in about a hundred years. Yet when we think of the many anomalous motions of the moon we cannot but have the most profound respect for the mathematical astronomer who can sift out from the intricacies of these anomalies such a marvelous solution of the problem of eclipses as noted above.

I trust this note will be of some use to my old-time friends of the SCIENTIFIC AMERICAN Too often my humble contributions on astronomical subjects are sadly distorted, and before they have traveled the rounds of newspaperdom have been made sensational, to my regret, but I am always content if I have added only a little to the sum of human knowledge and human happiness. JOHN A. BRASHEAR,

Beaumaris, Ont., Canada.

◆

The stirring of chemicals in the solution tanks of the Oberlin, Ohio, water softening plant, states the Engineering Record, is accomplished by the use of power furnished by a Pelton water wheel. The wheel is 12 inches in diameter, operates under a pressure of from 9 pounds to 22 pounds per square inch, and consumes about 50 gallons of water per minute. The wheel drives a main shaft, which drives the stirrers, or revolving arms, through the medium of a belt. The waste water from the water wheel is used for preparing the lime solution. The speed of the wheel is [illegible] revolutions per minute, of the lime agitator [illegible] revolutions per minute; and of the [illegible] [illegible] [illegible] revolutions per minute.

THE SEVEN BRIDGES OF KÖNIGSBERG AND OTHER PUZZLES.

BY L. P. [illegible]

The ancient and university town of Königsberg is situated on the river Pregel, which here forms an island called Kneiphof. There are seven bridges over the river, five of which connect with the island In the earlier part of the nineteenth century a discussion arose as to whether it were possible for a person to pass over all the bridges in one continuous trip and without covering the same path twice. In fact, this problem attracted the attention of the celebrated mathematician Euler In order to understand the question clearly, refer to the map The start may be made from any point. The problem is really insoluble, try however you will However, if it be considered allowable to cross the Pregel by the railroad bridge below the town, the problem may readily be solved Thus, beginning at a point on *D* one passes over the Holz Bridge, then over the Schmiede Bridge to the island, then back to *C* by the Krämer Bridge. One now makes a detour, passing over the Pregel from *C* to *B* by the railroad bridge, then passes to the island by the Grüne Bridge, returns over the Kötte Bridge, goes over the Hohe Bridge from *B* to *D*, and finally completes the journey by crossing the Honig Bridge onto the island. Thus, seven—in fact, eight—bridges have now been crossed and no part of the path has been covered twice.

This type of problem may fittingly be termed a *traveling puzzle* It is in reality a very ancient kind of thing Thus, there has come down to us from the time of Pythagoras, who flourished in the sixth century before the present era, a very simple example in the shape of the Pythagorean star an illustration of which is annexed, Fig 2. This figure may readily be traced by one continuous line and without duplication of the path

A story is told to the general effect that a disciple of Pythagoras once fell sick at an inn, where he was cared for very kindly by the innkeeper Instead of getting better, however, he grew worse. At last, with the expectation of dying and being unable to repay his kind host, the Pythagorean asked for a board. When this was brought, he traced out the single-line star Giving this to the innkeeper, he desired him that it should be displayed outside. Some time after his burial, a stranger happened along. Upon observing the star, he made inquiry, and was informed of the particulars related. He then, in order no doubt to make the story complete, handsomely rewarded the innkeeper for his unselfish care of the unfortunate Pythagorean.

THE SEVEN BRIDGES OF KONIGSBERG AND OTHER PUZZLES.

Another figure of the single-line type is that known as Mohammed's signature. This is shown in the annexed drawing, Fig. 3. It is understood to have been drawn by Mohammed upon the sand by a continuous and unrepeated movement of the point of his scimetar Beginning at *A* and following the course indicated by the letters *ABCDEFGA*, one may see how it was possible to accomplish this result.

An extension of the Pythagorean star is shown in Fig. 4. This may be solved by following the routes indicated by [illegible] it will be noticed that two or more [illegible] are taken consecutively If it be required that this shall not be the case, the problem is perhaps somewhat more difficult. Nevertheless, it is soluble, as may be seen by following out the order indicated by 14315325421.

We must not be deceived by the apparent simplicity of a given case of this type of puzzle. Thus Fig 5 discloses the very simple figure made by a circumference and two diameters. Try as you will, you cannot cover this figure by a continuous line that nowhere duplicates itself On the other hand figures that are apparently very complicated frequently admit of a ready solution Thus, the six pointed star shown in Fig 6 may be quickly solved by the method shown in Fig 7 To work the puzzle given by Fig. 8—that is, the star of Fig 6 with the including polygon—observe Fig 7 This does not in its present form, perhaps, suggest a solution for the reason that beginning and ending at the point indicated, we have no opportunity to draw the inclosing hexagon, either as a preliminary to starting or as a sequel to finishing But at the moment when we have arrived at the tip of *any* of the six points of the star we may draw this hexagon, and then continue according to Fig 7

Refer now to Fig 9 This is apparently a very complicated design. There is a very simple solution, however, which Figs. 10, 11, and 12 will assist in developing. It is easy to see how to draw Fig. 10, no matter where we elect to start. If we start at the tip of a point, the including polygon of Fig 9 may easily be drawn as a preliminary or a sequel (Fig 11) There is just one thing to see, and that is how the remainder of Fig. 9 may easily be made by forming a kind of loop at each of the inner points, *A*, *B*, *C*, *D* *E*, *F* (Fig. 11) The method of making this loop is indicated in Fig. 12.

To draw Fig. 13, we proceed as per Fig 9, except that the moment of arrival at *any* one of the points *G* *H*, *I* *J*, *K*, *L* is selected as the time to draw the innermost hexagon A complete solution is afforded by the course indicated by *M T H S N U I T O V J U P W K V Q X L W R S G* **H I J K L G** *X M* **N O P Q R M.** The heavy letters indicate where the innermost and outermost hexagons are added

Comparing Figs 5 and 13, it may seem hard to realize that one puzzle may be worked and the other not. Perhaps some readers may be inclined to think Fig 5 soluble An actual solution will of course prove that they are right. In the meantime the following considerations may prove of interest There are in all five junction points—*O* *A*, *B*, *C*, *D* If we do not start or end at such a point, we must recede from it for every approach and conversely for every recession there must have been a previous approach Approaches and departures are thus paired off At a starting point however it is possible to have a departure without a previous approach, this would occur when we begin, and only then Likewise at a finishing point, we may have an approach without a following departure, this would occur at the end and only then That is to say there can not be more than two points (the start and finish) where an odd number of lines join In Fig 5 there are *four* such points—*A* *B* *C* *D* This shows sufficient reason for pronouncing this figure insoluble

Let us turn now to solid bodies and look at some of the simpler cases Take the tetrahedron shown in Fig 14 It is certainly a matter of indifference at which vertex we begin so we start at *A* We have the choice of three beginnings It is also evidently a matter of indifference which of these we follow so we pass to *B* Here again the two possible choices are alike so we go to *C* Here the two routes lead to different results—*C* *A* completing a triangle (*ABC*) and *C* *D* closing no figure First we try *CA* Arrived at *A* we are compelled to go to *D* We have now two lines to draw—*D* *B* and *D* *C* We may cover one but not both So then we return to *C* and try *C* *D* Arrived at *D*, we see that if we go to *B* we shall be unable to go any farther So then we go to *A* and thus are forced to *C* Here we stop with *D* *B* undrawn. Referring however, to the discussion of Fig 5 we observe that the tetrahedron comes under the head of the impossible figures, as there are four points where an odd number of lines join viz. *A* *B*, *C* *D*

Fig 15 is likewise an insoluble case having eight points where three lines join Fig 16 is an apparent advance in complication But we observe that all six vertices are junction points for an even number of lines It is in fact a soluble case, as may be seen by following the course indicated by the numerals

Another variety of this same general class of puzzle is the problem which requires the knight to start from a position on the chessboard and cover the whole board by a continuous series of moves no position to be taken more than once. A convenient way of trying this puzzle is to rule with a sharp instrument on a slate the sixty-four squares of the chessboard Wherever you elect to start the knight you mark 1 His next position you mark 2, and so on. The slate cn ables false starts and errors to be readily corrected This kind of puzzle has attracted a good deal of attention and has received a multitude of solutions. Thus we may instance the solution given in Fig 17 Here the lower half of the board is covered before any beginning is made with the upper half The two halves are precisely symmetrical with each other, as may be seen by referring to Fig 18, where the path of the knight is indicated by a continuous line This division of the solution into two duplicates is not necessary but is an added refinement In one sense it simplifies matters as we have but half the board actually to solve We are restricted, however as to the point of termination Thus in the present example, the point of beginning 1 having been determined, the point 33—the beginning of the second half -is thereby fixed so 32 must come where it is at present or must be at position 6 Fig 19 is an illustration of a solution where the resulting arrangement of figures has some of the properties of a magic square Thus every column and every horizontal line sums up 260 If the diagonals each totaled the same number 260 then the whole would form a perfect magic square

◆

TERMINATION OF THE RHEIMS AVIATION MEETING

THE WINNING OF THE INTERNATIONAL TROPHY

As briefly noted in our last issue Glenn H Curtiss won the Bennett International Aviation Trophy on August 28th at Rheims. This trophy—a beautiful model of a Wright biplane held aloft by a female figure—was contested for the first time on the date above mentioned France being represented by two monoplanes -a Bleriot and an Antoinette—and one Wright biplane and America by one tiny biplane with a powerful 8-cylinder motor The real race was between Curtiss and Bleriot the champions of the biplane and the monoplane types of flying machines respectively and that the former accurately sized up his rival soon after he reached France is shown by the fascimile reproduction of the postal which he at that time sent our Aeronautic Editor

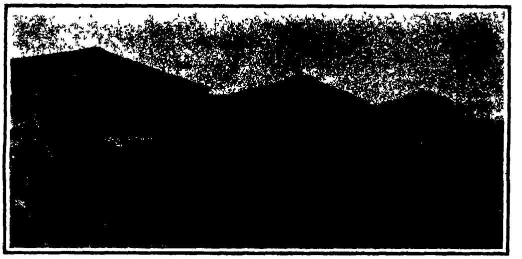
The morning of August 28th was mild calm, and hazy at Rheims. As the weather conditions were so favorable Mr Curtiss brought out his machine a few minutes after 10 and immediately started off on a preliminary round of the course Despite the fact that he made rather wide turns and that the aeroplane pitched considerably the time of the round was but 7 minutes 55 1/5 seconds—a decided improvement over Curtiss's former fastest round of 8 09 1/5 and 9 1/5 seconds less than Bleriot's fastest lap Mr Curtiss decided to try for the trophy at once His small gasoline tank was refilled more water was put in the radiator and after signing the official paper he quickly rose for the second time After circling around once in front of the grand stand he crossed the line at full speed The aeroplane still pitched perceptibly and the turns were with the exception of the very last one all rather wide but nevertheless both rounds were made in record time the second one being 4 1/5 seconds faster than the first and 2 seconds faster than the time in the trial flight The times of the rounds were 7 57 2/5 and 7 53 1/5 the total being 15 minutes 50 3/5 seconds which corresponds to an average speed of 47 04 miles an hour

The 4 1/5 seconds gain in time on the second round Mr Curtiss attributed to a slight change in the mixture which he effected by turning a small wheel he had conveniently at hand He ran the engine at its fastest speed all the time but during the second lap thought that it started missing explosions on one cylinder, so he made a slight adjustment. The pitching of the machine seems to have been due to the fast speed at which it was being driven in conjunction with the sensitiveness of the horizontal rudder control. When the machine would pitch downward and Mr. Curtiss would turn it upward again, the shock was so great that he said it was like striking a bump when riding in a fast automobile

The Curtiss biplane which won the International Aviation Trophy.

This machine made one circuit of the course at the rate of 47 78 miles an hour It traveled 18 63 miles in 15 minutes 50⅗ seconds (47.04 miles an hour) in winning the International Trophy

The other main event of the day—the Prix du Tour de Piste, or 10-kilometer speed test for one circuit of the course—did not bring out any contestants, since the two events could not be run together and since competitors were obliged to state for which prize they were competing But one trial was allowed for the International Trophy also After Curtiss's excellent flight, no other machines were brought out till about noon, when M Bleriot made a slow round with his 80-horse-power 'No 22' monoplane. About 2 P M. he tried another propeller, but only succeeded in making a round in 8 14 1/5 An hour later he had changed the 2-bladed propeller for a 4 bladed one He attempted to make a round, but was obliged to descend before completing it. After working at the monoplane where it alighted for over an hour with the aid of several mechanics, he at length flew back to his shed. As it was now almost 5 P M., and as no start was allowed after 5.30, he made hurried preparations for the test. It was 5 10 before the start was made. The monoplane flew splendidly without any rolling or pitching. The time of the first round was but 7 47 4/5, which was 5 2/5 seconds faster than Curtiss's second lap. If Bleriot could do as well in the second round, he would be the winner There was intense excitement among the spectators at the grand stand The machine finally rounded the last pylon The timers called the seconds remaining before his time would be up, but it was 5 3/5 seconds over Curtiss's 15 50 3/5 before the indomitable Frenchman crossed the line After conquering the Channel he had finally been defeated for lack of speed. Nevertheless, the performances of his and Latham's monoplanes remained unsurpassed for stability, even in strong winds The latter started in the cup competition just as Bleriot was finishing He flew at a great height—about 150 feet—and covered the course in 17 minutes, 32 seconds, thus securing third place. Lefebvre, the third French representative, with a Wright biplane fitted with a 40-horse-power motor, was fourth in 20 47 Mr Cockburn, who represented England with his Farman biplane, got half way around the course when the end of one plane struck a standing shock of corn whirling the aeroplane around and bringing it to the ground Latham met with a similar mishap afterward when carrying M Sariano as a passenger in the passenger-carrying competition This was won by M. Farman, who, after making a round with one passenger in 9 53 4/5, afterward carried two around the course in 10 39 2/5, or at a speed of 34 96 miles an hour The total live weight lifted by his machine was in the neighborhood of 450 pounds. A Wright biplane carried Franz Reichel around the course in 11 05 4/5 Farman's biplane was the only machine that succeded in carrying three people. Bleriot's 'No 12" monoplane, however, was the first aeroplane to accomplish this feat which it did at Douai last June, when a total weight of 1 234 pounds was carried at about 30 miles an hour with a 30-horse-power motor Farman's biplane had a 50-horse-power Gnome revolving-cylinder motor This engine was fully described in SUPPLEMENT No. 1729



The Bleriot monoplanes in front of their sheds.

The No 22 machine was fitted with an 80 horse-power 8-cylinder motor It made the fastest round of the course at the rate of 47 78 miles an hour

In addition to winning the International Trophy Mr Curtiss, the following day, carried off the first prize ($2,000) in the 30-kilometer speed contest, known as the Prix de la Vitesse. His first attempt was made early in the afternoon The three rounds of the course were made in 24 minutes 15 1/5 seconds. Believing that Latham had made better time, he made another attempt. This time he made very short turns and drove his machine at even greater speed The three rounds were made in 7 49 2/5, 7 48 2/5, and 7 51 1/5, the total time for the three laps being 23 minutes and 29 seconds, or a speed of 47 6 miles an hour The second lap was made at a speed of 47 73 miles an hour, which was the fastest time for the course by any machine, with but one exception Because Mr Curtiss did not start in this contest on the first day of the meeting he was penalised 1/20th of his actual time, so that his official figures were 29 minutes and 48 seconds. Latham made another attempt to better his previous record, but in this he was unsuccessful.

Bleriot started about 10 o'clock with the intention of making another trial in this competition. He crossed the line and made the first turn at a rapid rate, flying at a low elevation. He finally [illegible]

Weight of the aeroplane loaded 700 pounds, total surface 335 square feet. Speed 47 78 miles an hour Thrust developed by propeller, 260 pounds.

THE RHEIMS AVIATION MEETING

view at the far end of the long side of the course. It was supposed that he had passed out of view in the depression at this point, which was called by Curtiss the "Aeroplane Graveyard" on account of the strong wind currents there and the many machines which met with accident at that point. Soon, however, a column of smoke arose, and upon going to the spot in an automobile it was found that Bleriot's machine had dived to the ground, caught fire, and was rapidly being consumed. M. Bleriot was rather badly burned and received numerous bruises. His only explanation was that something must have broken about the rear horizontal rudder, which caused him to lose control of the machine so that it dashed to the ground The gasoline tank was broken and the fuel quickly ignited from the motor

Another machine which was wrecked at this time was a rather heavy biplane built and flown by M Louis Bréguet This machine made its short flight the evening before. On Sunday morning a short flight of about 300 feet was made, the machine alighting without injury The next time flight was attempted, however, the machine shot upward to a height of about 100 feet and, after traveling a short distance and dipping to the right, it descended at a sharp angle until the low end of one plane struck the ground and swung the machine around, while it at the same time reared up on its prow Fortunately, M Bréguet was not injured

The results of the Prix de la Vitesse were therefore as follows

First, Glenn H Curtiss, with his 60-horse-power biplane. Time 23 29, official time with penalization 25 49 2/5

Second, Hubert Latham, with "No 29 Antoinette monoplane Official time, with penalization 26 33 1/5

Third, Tissandier with his Wright biplane Time 28·59 1/5

Fourth, Lefebvre, with a Wright biplane Time 29 minutes.

Fifth, Count de Lambert, with a Wright biplane. Time 29 02

Sixth, Latham, with "No. 13" Antoinette monoplane. Time, with penalization, 29 11 3/5

Seventh, Paulhan, with a Farman biplane Time 32;49 4/5

Eighth, Bunau-Varilla, with a Voisin biplane, Time, with penalization, 42 25 4/5.

The other speed contest, the Prix du Tour de Piste, which was for one circuit of the 10-kilometer (6.21-mile) course was won by M. Bleriot, who covered the distance in 7 47 4/5 (47 78 miles an hour) Curtiss's time of 7 48 2/5 for one round in the Prix de la Vitesse gave him second place in this contest.

The Prix de l'Altitude or Height Competition ($2 000 prize) was won by Latham who reached a height of 155 meters (508 5 feet) as recorded by a barometer upon his monoplane Farman was second with a height of 110 meters (360 9 feet), Paulhan third with 90 meters (295 3 feet) and Rougier fourth with 55 meters (180 4 feet)

The Prix des Mecaniciens was won by M Bunau Varilla with a distance of 100 kilometers (62 1 miles) to his credit while M Rougier was second with 90 kilometers (55 9 miles)

The Prix des Aeronauts ($2 000) for the fastest five circuits of the course a total distance of 50 kilometers (31 06 miles) was won on Sunday by the large dirigible 'Col Renard" the time being 1 14 49 The smaller dirigible 'Zodiac" covered this distance in 1 25 01 The average of the winner was 24 9 miles an hour

A NOVEL CANTILEVER GRAIN ELEVATOR.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

The discharge of grain from the holds of vessels economically and efficiently, as well as expeditiously is a problem which involves the solution of many problems of a peculiar character During the past few years many developments in this direction have been carried out at the discharge ports of England in the handling of the grain received from abroad especially in regard to the port of London There the conditions are probably unique, for not only has the grain to be discharged from the vessel's hold to dock elevators, but also to lighters and other craft for conveyance by water to numerous other points

Many applications have been devised from time to time for accomplishing this work to the best advantage and recently conspicuous interest has been centered in a new cantilever elevator with which the grain handling equipment of the London Grain Elevator Company of Silvertown E has been reinforced This plant has been designed by the grain company's engineer Mr Alfred H Mitchell to whose courtesy we are indebted for the accompanying illustrations and information and its operation and convenience in working has compelled general approval It is designed for discharging grain from a ship s hold to accompanying craft and as may be seen from the illustrations it is of the self propelling pontoon contained type It is so constructed that it can be brought to work either side-on or end on to the ship and has the additional advantage when working end-on that it can deliver to two barges at the same time whereas should the conditions such as a narrow dock or a tideway necessitate its being worked side-on its advantages are in no way less

The outstanding feature of this apparatus depends not so much upon the formation of the elevator proper as upon the mechanical combination of levers whereby it is manipulated As is well known, the conditions of working grain from ocean going steamers vary very considerably in point of size of the steamers to be unloaded and the manner in which the grain is stowed On commencing to discharge the grain being right up in the hatchway is probably at a height of some 15 or 20 feet above the waterline necessitating the means of putting the lower end of the elevator into the grain at this height and delivering in the manner required Shortly afterward when the elevator has sunk well into the cargo of grain the bottom point may require to go as low as 20 feet below the waterline that is to the bottom of the ship

When the vessel is discharged it is necessary to lift the bottom end of the elevator over the highest point of the ship s coamings which may then be as much as 40 feet above the waterline This means that the lower or digging end of the elevator must have a vertical range of some 60 feet to comply with the foregoing conditions It is equally apparent that the clear length of the leg below the supporting arm must be sufficient to bottom the deepest hold of any ship which may extend to 40 feet for a moderate-sized steamer and of course much more in some ocean going grain carriers. Another vital factor in connection with the ship is the width of beam Most craft being divided by longitudinal partitions placed amidships, and in the after hold by a tunnel over a propeller shaft it is of the utmost importance that the elevator should be adaptable to working on either side of the ship's center line

The general method by which this end is accomplished is either by means of a portable machine lifted into the ship by means of the latter's boom and resting upon beams placed across the hatch coamings or by means of a pneumatic machine The first is accompanied by grave risk in lifting the machine in and out, and moreover is slow and costly in operation owing to the time involved in installing the appliance and removing it when done with the time consumed in this operation often being in excess of that occupied in withdrawing the grain. With the pneumatic machine great expense is incurred in manipulation, owing to the enormous wear and tear as well as the horse-power required, though it is admittedly useful for dealing with awkward stowages, such as in forepeaks and lazarettes

The peculiar conditions prevailing therefore can best be met by some such appliance as this new cantilever system which is independent of the ship's gear, excepting in so far as the latter is used for plowing the grain to the leg of the elevator after it is lowered into the hold. In ordinary discharge elevators an arm of considerable length is fitted to the top of a tower, and counterbalanced by a weight mounted on the back end. In floating elevators, the disadvantage of this arrangement is that in the first place the enormous topweight necessitates the use of a very large pontoon, and secondly, that owing to the radius of the arm being definitely fixed, it cannot be adapted to ships of different widths, or for working to port or starboard of the partitions referred to, except by the slow and difficult process of booming the barge off from the ship, or the ship off the quay if the latter type of machines are used.

The first development in the evolution of the cantilever elevator was the bringing down of this top balance weight, and carrying it on levers at the back of the post. If the lever be equal in length to the back end of the jib, and the suspending link be equal in length to that portion of the post above the link, a parallel motion results, whereby the weight is moved equally with the back end of the jib, and balances it as before The result of this arrangement is that the top weight formerly required to balance an effort of some 400 foot-tons in an ordinary-sized machine, is greatly reduced, which brings about a corresponding reduction in the dimensions of the pontoon.

The final development of this design by Mr. Mitchell is that shown in the accompanying photographs. Here the post, which in the former designs was rigid, is now itself supported by a trunnion at the top of a frame, which is mounted on a turntable on the pontoon deck. By this combination it becomes possible to shorten the length of the cantilever arm by the amount which the vertical post could swing forward, thereby not only bringing about an appreciable reduction in the weight of the cantilever jib, but also reducing enormously the amount of weight which is required to balance it. Assuming the elevator leg to be perfectly balanced by the jib balance weight, the center of gravity of the whole combination will pass through some definite point on whichever side is uppermost of the post. This point being found, it becomes possible by ballasting the lower end of the tilting post to bring the center of gravity of the whole combination to the middle of the trunnion pin, at which point it will remain, no matter what the position of the elevator This arrangement not only secures the bringing down of the weights to a very low point, but by means of the compound balance thus obtained, the elevator can be worked side-on or end-on, in broad or narrow ships, without imparting to the barge the slightest tendency to list or alter trim, so that a very small pontoon can be used to carry it. The smaller the dimensions of the latter can be made, the easier it is to handle and tow, and what is more important, the less space it occupies at the ship s side or in dock This is a distinct advantage in connection with ocean liners, where often general cargo has to be handled at the same time as grain is being discharged

In actual practice the full weight of the elevator leg is not absolutely balanced, there being a certain excess allowed on the elevator end for sinking the leg into the grain This excess in the ordinary way would produce a list or alteration of the trim of the pontoon, and so in order to counteract this, a weight is fixed under the turntable at a certain distance aft of the center line, and of such proportions that the amount of the weight multiplied by that distance is equal to the excess moment of the other side As a result the horizontal balance remains constant and perfect, and will not produce any list so long as the cantilever jib remains horizontal When the jib is raised or lowered out of the horizontal, however, it will be apparent that there is a very slight alteration of moments, which however is not sufficient to produce any perceptible alteration of trim in the pontoon.

The elevator shown in the accompanying illustrations is among the first of its type to be constructed on these lines, and is now doing duty in the elevator dock on the Thames at Silvertown. Its leg is telescopic, and has a length when extended of 41 feet clear under the suspending pin. The buckets are carried upon an endless chain, and are so arranged that as the telescopic leg is lifted, the exact amount of chain that is let out on the front of the leg is taken up in the back, so that the chain remains of the same length and of an even tension throughout. The buckets, which are 10½ inches apart, have a capacity of 100 tons of wheat per hour, working at full speed, and deliver at the rate of 320 buckets per minute.

The elevator, carried at the end of a cantilever jib, is 35 feet long center to center, 9 feet 6 inches at the back end, and the weight of the leg is partly balanced by the weight at the back, connected by means of the parallel bars and lever shown and already described. The grain is discharged from the elevator head by means of suitable adjustable chutes on to an endless conveyer band, carried on the inside of the jib. This band is of canvas with rubber on one side, and is provided with flanged ribs [illegible] to facilitate the grain [illegible]

The elevator at rest upon the pontoon's deck for transit. This view well shows the parallel motion of cantilever arm and balance weight.

The elevator in mid-position as it would be when half way down into a ship's hold.

A NOVEL CANTILEVER GRAIN ELEVATOR.

[illegible] into its lowest position. These ribs are placed diagonally, to permit them to run freely over the supporting rolls, which carry the slack side of the belt. At the top of the post this belt discharges into a second receiver, which by means of the long telescopic chute shown discharges into the boot of a second elevator, which is placed on the deck, which in turn raises the grain and empties it into the weigh-house or hopper, from which it is delivered to lighters alongside.

The jib of the elevator is carried at the top of the inclined post, which in turn is supported at the trunnion pin at the top of the frame, which rotates upon the turntable, the supporting ring and rack of the latter being secured to the bottom of the craft. The length of the tilting post above the trunnion is 30 feet, and the height of the trunnion pin above the bottom of the pontoon is 17¼ feet. The weigh-house is fitted with six automatic grain scales of 250 pounds capacity each, and these can discharge into sacks or loose into lighters, as may be desired

A noticeable feature of the machine is the celerity and facility with which it can be brought in and out of action. Once it is moored alongside, the leg can be swung round and lowered into the hold ready for working within about four minutes, and this is considerably less than is possible by any other method. A portable machine to be rigged up ready for working takes from two to three hours, according to the position of the ship's winches and the weather Moreover, the great advantage of facility for instant adjustment of the elevator to any width of ship, or for lifting the leg instantly from one side of the ship to the other over shifting boards or propeller tunnels, is perfectly obvious. Again, not only does this machine render possible the use of a single instead of a double leg, but in the event of there being hatch-beams or other obstructions in the hold, it facilitates the placing of the leg in the position required immediately, while in a big hatchway the possibility of being able to sweep the hatchway to its full extent with the combined movements of slewing and post tilting, thereby saving a considerable amount of trimming, is a conspicuous advantage. The exact adjustment of the telescopic leg or the height of the jib also makes it possible to work different consignments of grain in the same hold which are only separated by mats or cloths, as the depth at which the leg is to work can be adjusted to a nicety As may be seen in the illustrations, the combination of the two levers and the telescopic leg gives a great range of action.

The precise angle of the jib is controlled by means of an electric winch and wire hauling gear, acting on the back end of the jib while the tilting of the post is performed by means of a screw and nut carried in a bracket near the trunnion pin of the post. All the controlling actions are performed by series-wound motors of 4 B. H P, and the elevator is driven by a 20 B. H P motor attached to the turntable The direct current at 110 volts is generated on board the pontoon by means of a gas engine and suction gas plant driving a dynamo by belting. The deck elevator is driven from a countershaft in the engine room and a chain belt as described.

The whole apparatus is controlled by one man for whom a cabin is provided on the turntable. A deckhand assists in adjusting the chutes when getting the elevator to work, and afterward attends to the suction gas plant. The maneuvering requirements of the machine are signaled by a man on the grain vessel's deck, who indicates the exact desired position of the elevator, and follows its operation

◆

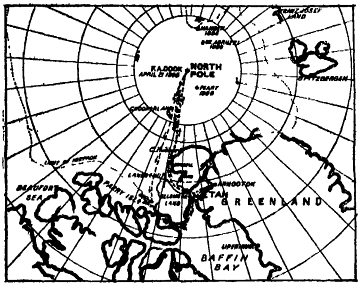
DR. COOK'S DISCOVERY OF THE NORTH POLE.

The search for the North Pole, which began in the Middle Ages for the purely commercial purpose of finding a sea passage to the wealth of the Orient, and which continued to attract adventurous and scientific spirits long after a more direct route to the Far East was discovered, seems to have culminated in the success of Dr. Frederick A. Cook, of Brooklyn, N. Y. Dr. Cook announced the remarkable result of his expedition in a telegraphic dispatch sent on August 24th from the Shetland Islands, where he stopped for two hours on his way south to Copenhagen Although no definite scientific proof is as yet available of Dr Cook's claim, there can be but little doubt of his great triumph. His previous experience in Arctic exploration and his acknowledged intrepidity are conceded even by those geographers who are disposed to await his arrival at Copenhagen.

Dr. Cook's polar expedition seems to have been quite unpremeditated. In 1907 he accompanied John R. Bradley, a wealthy sportsman, on an Arctic shooting trip in a small converted Gloucester fishing schooner When they arrived at the limit of navigation in Smith Sound late in August, 1907, the conditions seemed so favorable for a successful polar dash that Cook determined to make the attempt. In that venture he was undoubtedly favored by a combination of fortunate circumstances. Many Esquimaux had gathered on the Greenland shore at Annootok for the annual bear hunt Great quantities of meat had been brought in by the hunters. Dogs, too were numerous Since food and dogs were plentiful both prime requisites in any polar expedition, Dr Cook promptly decided to make an attempt to reach the Pole, 700 miles distant. The entire village of 250 people fell to and fitted him out, so that before the end of the long winter night he was ready to set out and to follow a route of his own choosing over Grinnell Land and northward along its west coast out on the polar sea.

The expedition started on February 19th 1908, with 11 men and 103 dogs drawing 11 sledges. At the very outset the usual hardships of the Arctic explorer were encountered The crossing of Ellesmere Sound was accompanied by a drop in the thermometer to 83 deg. below zero Fahrenheit. Several dogs were frozen to death Eventually Land's End was reached Game was plentiful In this march to Land's End no less than 101 musk oxen 7 bears and 335 hares were killed, there was no lack of fresh meat

At a point 460 miles from the Pole Cook sent back all his Esquimaux but the two most capable and all his dogs but 26 On March 21st the final effort began A great stretch of open water was crossed—how Dr Cook does not tell us in his dispatch Presumably he used a collapsible canvas boat, which he casually includes in the description of his outfit. On March 30th new land was discovered in latitude 84 deg 47 min longitude 86 deg. 36 min No time was lost in exploring the new country This was the last land that Cook traversed. Thereafter his course lay on the frozen polar sea.



THE COURSE FOLLOWED BY DR. COOK AND HIS IMMEDIATE PREDECESSORS

The game which had previously been so plentiful was conspicuously absent Even microscopic life could not be found. Curiously enough, the surface of the ice pack opposed fewer obstacles than at the outset On the other hand, violent winds hampered him On the night of April 1st, 1908 the sun appeared at midnight over the northern ice The next day found Cook at latitude 86 deg. 36 min and longitude 94 deg 2 min In other words, he had covered about 100 miles in nine days and was 200 miles from the Pole.

Dog after dog was killed to supply the other animals with food as well as Cook and his companions On April 14th latitude 88 deg 21 min and longitude 95 deg. 52 min. was reached The pole was 100 miles away The few stretches of open water were covered with young ice, so that no difficulty was encountered in crossing them.

On April 21st the first corrected altitude of the sun gave 89 deg. 59 min 46 sec. The Pole was only a few miles distant. The remaining 14 seconds were covered by April 21st, 1908, on which day Cook planted the American flag at the North Pole, or rather on a shifting bed of ice which was then at the North Pole

Cook remained at the Pole for two days On the 23rd he started back Keeping his course well to the southwest, in order to allow for the easterly drift, he covered considerable distance during the first few days. Food became so scarce that for a time it seemed questionable whether Cook and his companions would not perish by starvation. Cloudy weather an indication of approaching summer as well as violent gales made his journey southward difficult. Eventually he reached Crown Prince Gustav Sea, with its vast expanse of open water Fortunately, a few bears were shot, and the diminished food supply was replenished. In July Cook crossed the Firth of Devon into Jones Sound Eventually Cape Sparbo was reached, where game was plentiful An underground den was dug, in which Cook and his companions lived until sunrise of 1909 February 18th a start was made for Annootok and the Greenland shores were reached on April 15th

Contrasting Cook's achievement with Peary's exploit of 1906 in which year Peary reached latitude 87 deg. 6 min 200 miles from the Pole we find that Peary started about three weeks earlier in the season Cook's outfit was probably inferior to Peary's hastily prepared as it was. Peary was compelled to turn back because of the great stretch of open water that confronted him Cook was undeterred by water possibly because he carried with him the canvas boat mentioned

Peary's attempt is particularly interesting because Dr Cook started out with the avowed intention of avoiding some of the drawbacks which had beset Peary One of these drawbacks was the general set of the floe to the eastward, with which Peary had to contend Dr Cook, it is understood struck off to the westward for the purpose of making allowance for this floe when he started on his direct north route

Dr Cook is not a novice at exploration He was surgeon and ethnologist in the first Peary expedition in 1891 92, assistant in command of the Miranda expedition which ended in disaster in 1894 surgeon and anthropologist of the Belgian Antarctic expedition which was gone between the years 1897 and 1899, and surgeon in the Peary expedition of 1901 This record must be amplified by the inclusion of his feat as the first conqueror of Mount McKinley in Alaska about which there has been some controversy

It is the prevalent view among geographers that there is no land in the neighborhood of the North Pole This opinion is based upon the fact that no Arctic land is known to rise except from the continental shelf or from comparatively shallow waters But north and northeast of Franz Josef Land the "Fram" expedition under Nansen found depths of 2 000 fathoms or more and fifty miles to the north of Alaska the Nikkelsen-Leffingwell expedition was unable to reach bottom with its sounding line which measured 2 060 feet These and other ascertained facts have encouraged the belief that there is no land around the North Pole Dr Cook now confirms these geographical surmisings.

The mere quest for the Pole itself is not regarded even by Arctic authorities as an especially worthy undertaking What are the conditions of the sea and its currents the air the ice the life of the region and other phenomena between the known Arctic and the Pole? The answer to such questions as these is what is expected in these days of trained explorers No doubt Cook will be able to add much to our scant knowledge on these points

The Norsemen probably were the first Europeans to visit the Arctic regions and Greenland The struggles to find a short cut to the riches of the Far East were more productive of adventures and loss of life than the latter-day dashes for the Pole Perhaps the earliest of scientific explorers was Sir Hugh Willoughby who sailed in 1553 "for the search and discovery of northern parts of the world" He discovered Nova Zembla, but starved with most of his men in Lapland on the return voyage

The following explorers emulated him

	Deg	Min
1588—John Davis England ship	72	12
1594—William Barents Holland ship	77	20
1607—Henry Hudson England ship	80	23
1616—William Baffin England ship	77	45
1773—J C Phipps England ship	80	48
1806—William S Scoresby England ship	81	30
1827—W A Parry English sledge	82	45
1852—E A Inglefield England, ship	78	21
1854—E K Kane American sledge	80	10
1868—K Koldeway Germany ship	81	5
1870—C F Hall American ship	82	11
1871—C Weyprechte Austrian sledge	82	5
1875—G S Nares, England sledge	83	20

1906—R E Peary American sledge	87	6
1908—Dr Cook, American sledge .	The pole	

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

COAT HANGER.—I. Frentman, New York, N. Y. This invention relates especially to the cords or chains which are attached on the inner side of the collar to enable the same to be hung upon a hook. The purpose is to provide an anchor plate which can be readily secured to the material of the garment. There are two of these anchor plates provided and they are connected by a chain.

Electrical Devices.

IGNITER.—G. W. Sage, Eureka, Cal. The improvements are in igniters for use in connection with internal combustion engines and more particularly to that type of igniter in which two electrodes are brought into contact and then separated at the instant it is desired to produce the spark. It relates to that type disclosed in the previous patent granted to Mr. Sage.

TELEPHONE MOUTHPIECE.—G. H. Reed, New York, N. Y. The invention refers more particularly to means for rendering the mouthpiece antiseptic and for increasing the volume of the sound transmitted. The diaphragm and pad may be readily removed or replaced and the mouthpiece in presenting a large bell-shaped outer end increases the effect of the voice upon the diaphragm of the transmitter.

ROTARY CONVERTER.—J. L. Murdock, Boundbrook, N. J. Mr. Murdock's invention pertains to so-called "current shaping mechanism," his more particular object being to produce a converter for selecting from three-phase alternating currents predetermined portions of said currents in such manner as to accumulate the effect of the portions thus selected and thus build up a virtually direct current which is practically constant.

Of Interest to Farmers.

GIN COTTON-SEED CLEANER.—H. A. Moss, Kennett, Mo. This cleaner is a shaking screen for cleaning gin cotton-seed by removing therefrom hulls, loose cotton, dirt, and sand. It is adapted and used for securing cotton-seed discharged from the gins, and separates from the seed the cotton and hulls which are conveyed to a storage bin, the cotton being subsequently returned to the gin to be re-ginned, whereby an important saving is effected.

THERMOMETER HANGER FOR INCUBATORS.—O. H. Lee, Omaha, Neb. In this case the invention refers especially to thermometers when used in incubators or in similar situations where it is desirable to have the bulb supported adjustably so that the level of the bulb may be regulated and placed at any point desired.

PLOW.—S. A. Estabrook, Jr., Ponchatoula, La. In the present patent the invention is in plows and has for its purpose to provide means to vary the sweep of the plow, whereby the soil may be thrown from furrows close to growing plants at each side and the plow thus used for different spaced rows.

Of General Interest.

CAMERA.—A. L. Richardson, Melrose, New Mex. This invention has reference to improvements in photographic apparatus and is applicable chiefly to cameras used in photographic studios for the purpose of making portraits; also it may be used with other cameras such as those used for taking landscapes or for other outdoor photographs.

HIGH-SERVICE DAM.—R. Griswold, Denver, Colo. The purpose here is to provide novel details of construction for a high service dam that adapt the dam for erection in a gorge or canyon near the highland so as to arrest a portion of the water drained therethrough and produce back water for irrigation of the soil over which the arrested water is returned.

EAVES-TROUGH.—Lizzie H. Dickelman, Forest, Ohio. The aim in this instance is to provide a construction whereby to increase the strength and rigidity of the trough when the sections are coupled together and at the same time to provide a construction in which the process of manufacture is simplified and in which the sections may be more quickly and easily put together and disconnected when desired.

Hardware.

NAIL-HOLDER FOR HAMMERS OR HATCHETS.—W. E. Wieland, Durango, Col. One purpose here is to provide details of construction for the handle of a nail driving tool such as a hammer or hatchet which convert the handle into a magazine wherein nails of a selected dimension may be carried and by a shaking movement of the handle be passed through a longitudinal slot in the hollow body thereof and hang by their heads projected from the slot, to be manually removed as desired.

Heating and Lighting.

INCANDESCENT-LAMP SOCKET AND SWITCH.—T. L. Cash, Portland, Ore. This invention relates to incandescent lamp sockets and the intention of the invention is to improve the construction of the socket and particularly that of the switch for turning the lamp on or off. Means are provided for making signs visible that indicate that the current is turned on or off.

CONDENSING SYSTEM.—S. Woolf and C. W. Rafferty, Lynch, Neb. An object of the invention is to provide means for disposing of the exhaust steam by condensing the same, thereby providing means for overcoming back pressure. Means also provide for removing impurities carried along with the steam, thereby leaving the feed water in a pure condition for immediate re-entrance into the boiler.

Household Utilities.

SAD IRON.—G. P. Clements, New Milford, Pa. The iron has an adjustable extension adapted for opening and pressing seams, ruffles, tucks, etc. In retracted position the extension conforms to the outward contour of the iron. It retains heat much longer than small irons, yet is capable of ironing small and complicated work even more thoroughly than small irons, besides avoiding the necessity of having several sizes of irons.

BED ATTACHMENT.—H. L. Appleton, Shelby, Ala. In this patent the intention of the improvement is the provision of an attachment for hospital beds or the like, easily removed or replaced, for containing sponges and instruments, and so arranged as not to interfere with the use of the Kelly pad or similar drainage devices.

CURTAIN FIXTURE.—J. Darling, Chicora, Pa. The improvement here is particularly in that class illustrated in Mr. Darling's former patent. The construction permits the convenient utilization of the ordinary curtain rollers on the market and provides for securing the same in the hook bracket in such manner as to prevent any accidental displacement of the shade when applied for use.

CLOTHES-DRYING DEVICE.—J. M. Teach, Santa Monica, Cal. The aim here is to provide a drier erected in the open air which affords a device that is very convenient in use and well adapted for the reception of a considerable number of pieces of clothing or other fabric that are to be exposed to the sun and air.

Machines and Mechanical Devices.

CUTTER HEAD.—J. F. Stedman, Newburg, Ore. Mr. Stedman's invention has for its more particular purpose the provision of an improved mounting for securing the cutters upon the cutter head in such a manner that the cutters may be readily attached and detached at will and may also be adjusted as desired without removing them from the cutter head.

WAVE MOTOR.—C. W. Hicks, Los Angeles, Cal. A purpose of this inventor is to construct a motor particularly automatic in action wherein a pier is built out into the ocean or equivalent body of water a desirable distance, in connection with which tracks are employed, having an inclination upward in direction of the shore, upon which tracks a motor carriage is adapted to travel.

WIND MOTOR.—C. Dair, New York, N. Y. The more particular purpose of this invention is to provide a type of wind motor in which there are two sets of wind wheels turning in planes which cross each other, the combined effect of all of the wind wheels being transmitted ultimately to a shaft or other driven member common to all of the wind wheels.

FILLING DEVICE.—E. N. Gaudron, Hasbrouck Heights, N. J. The object here is to provide a device more especially designed for filling bottles and other receptacles with liquids contained in kegs, barrels, vats, tanks and other storage vessels, and arranged to automatically stop the filling at the time the bottle is filled, to prevent the return flow into the storage vessels and thus avoid displacement of sediment.

REDUCING VALVE.—T. P. Ford, New York, N. Y. The valve is more especially designed for high pressure fire systems and the like, and arranged to permit variable pressures from a common supply, such as a hydrant, to allow, for instance, use of several hose of low and higher pressure for outside work. Use is made of a valve casing having a connection with the hydrant or other water supply and provided with a plurality of outlets for connection with separate fire hose, and main piston valves arranged within the said valve casing for controlling the flow of water to said outlets.

Prime Movers and Their Accessories.

FLUE CLEANER.—J. Winchmann, Albany, N. Y. This cleaner thoroughly cuts the scale from the inside of the flue or tube by the use of a cutter head rotating with the turbine wheel and provided with a cutter wheel mounted to rotate loosely on the end of a centrifugal swing arm, so that the center pin of the turbine wheel is relieved of undue strain and a proper cutting of the cutter wheel is insured without danger of breaking the latter or causing it to stick in the scale.

Designs.

DESIGN FOR A PICTURE-FRAME.—A. Kaiserman, Rochelle, Ill. This neat ornamental design for a picture frame comprises a frame of an inverted kite shape, the frame standing by a prop support on a flat surface. A cord and tassel hangs from the top point, and a tube-shaped projection extends from the center of the article.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12121) O. M. T. asks: A local steam plant has been supplying steam for some time to several power plants in this city. They have two boilers of 100 horse-power each. They have been supplying about 200 horse-power steam through a 4-inch steam line about 500 feet long. To do this took altogether too much coal. They used about eight tons per day. They dropped off 100 horse-power of this load, and it only takes three tons or less per day, using one boiler only. What is the explanation? Would the size of steam pipe make any difference in the amount of coal used? A. The size of the steam pipe might easily affect the coal consumption per horse-power generated. Without further particulars as to the distribution we cannot say exactly, but supposing that half or more of the total horse-power is consumed by engines half or more of the total distance from the boilers, a 4-inch main is certainly small enough to cause an appreciable loss of power. It is probable, however, that the boilers are overloaded, and a reduction by half of the power consumption might well cause a greater proportionate reduction in the fuel consumption.

(12122) C. H. P. asks: We have two tanks lying horizontally. One is 6 feet 6 inches in diameter and 29 feet 6 inches long and there is 24½ inches of oil in this tank. The other is 6 feet in diameter and 25 feet 8 inches long, with 32¾ inches of oil (from bottom of tank to top of oil). How many gallons in each tank? Please give formula used if possible. A. Your question is not very clear, as you refer to the distance from the *bottom* of the tank (usually meaning the circular flat bottom) to the top of the oil, but as you refer to the tanks as lying horizontally, we presume you mean that the axis or longer dimension is horizontal and mean by the bottom the curved side of the cylinder lying on the ground. In this case the volume of the oil is the product of the length of the tank by the area of the segment of a circle of which the surface of the oil is the chord. The area of such a segment is calculated by the formula

$$\left(A = \frac{4h^2}{3}\sqrt{\frac{D}{h} - 0.608}\right)$$

in which A is the area, h the height of the segment (in your case the depth of the oil) and D the diameter of the circle of which the segment is part. The derivation of the formula is difficult, involving higher mathematics which you presumably do not want, but its results are very closely approximate. In your first case $D = 6$ feet 6 inches $= 78$ inches, and $h = 24.5$ inches, so

$$\left(A = \frac{4 \times 600.25}{3}\sqrt{\frac{78}{24.5} - 0.608} = 800.33\sqrt{2.576} = 800.33 \times 1.605 = 1284.5 \text{ square inches.}\right)$$

So the volume of the oil is $1,284.5 \times 29$ feet 6 inches $= 454,713$ cubic inches $= \frac{454,713}{231}$ gallons $= 1,968$ gallons nearly. With the above example you can easily calculate the second amount, substituting $h = 32.75$ and $D = 72$ inches, and multiplying the area found by 25 feet 8 inches.

(12123) P. O. B. 35 asks: Does a 22-horse-power automobile develop more horse-power in "low" than in "high"? I am sure it does not, but just to prove it to the fellow with whom I am betting I am asking you. Do you answer by letter or in the next Scientific American following the receipt of the question? A. We make it a rule not to settle bets, but as we can only guess at the meaning of your question we do not mind stating a general principle from which you can draw your own conclusions. Supposing that your question has some reference to the change-speed gear of an automobile, no amount or kind of gearing can alter the power generated by any engine. If a man can lift 100 pounds through one foot in a second with his hands, but can raise 1,000 pounds with a fall and tackle, he must continue for ten seconds expenditure of the same amount of energy per second required to raise the smaller weight in order to raise the 1,000 pounds 1 foot, because where he gains in mechanical advantage, he loses in speed. In the same way with an engine, if a certain number of revolutions producing through gears a given torque on the wheels will drive a car 20 miles an hour along a level road, a greater torque is required to drive at even a much less speed up a steep grade. The engine speed is therefore reduced by the increased load, and, as a high speed is necessary for efficiency in gasoline engines, a change of gear is made which allows the engine to run as fast as before while the wheels turn more slowly, thus distributing the same amount of work over a longer period and overcoming a heavier load; but the power generated is the same, power being the work done divided by the time consumed in doing it. This is not to say that the output in brake horse-power of an automobile or any other engine is always the same, but merely that it cannot be affected by the gearing.

NEW BOOKS, ETC.

Modern Accounting. By Henry Rand Hatfield. New York: D. Appleton & Co., 1909. 12mo., 367 pp. Price, $1.70.

This is a most valuable treatise, giving in lucid style the best principles of accounting. The essence of accounting from the author's viewpoint is the presentation first of a careful exhibit of a definite status of the concern at a given moment of time, and secondly a showing of the results obtained during a given period of time. The first is embodied in the balance sheet, the second in the income or profit and loss statement. The presentation of a correct view of a concern's financial status and of its past profits involves many points of theoretical interest and practical import. The present volume will do much to give those who are charged with the ultimate revision of figures most valuable information. The chapters relate to Principles of Double Entry Bookkeeping, Balance Sheet, Assets and the Principles of Valuation, Valuation of Particular Assets, Mutual Assets, Depreciation, Capital Stock, Liabilities, Profits, Surplus and Reserve, Sinking Funds, Trading, Manufacturing, and Income Accounts, Cost Accounts, Partnership Accounts, Statement of Affairs and Deficiency Account, Technical Improvements in Accounting Practice. The subjects treated are very well arranged and the book will certainly be of great value to the heads of business corporations as well as those who are charged with the actual accounting.

Handbuch für Heer und Flotte. Enzyklopädie der Kriegswissenschaften und verwandter Gebiete. Herausgegeben von Georg von Alten, Generalleutnant z. D. Vollständig in 108 Lieferungen reichillustrierten Textes mit farbigen Beilagen, Karten, Plänen, Gefechtsskizzen, etc. Deutsches Verlagshaus Bong & Co. Price per part, 50 cents.

The last five installments of this admirable military and naval encyclopedia contain some excellent articles on tactics, most of them historical in treatment and some based upon the results of the recent Russian-Japanese war. Among these may be mentioned the articles entitled "Aufklaerung," "Aufmarsch" and "Ausdehnung der Gefechtsfront." Some excellent articles on historical battles and sieges are to be found under the headings "Aspern," "Austerlitz," "Bayaume," "Bar sur Aube," "Bautzen," "Atb," "Badajos," and "Barcelona." European military geography is also discussed, particularly under the headings "Athen," "Baden," and "Bayern." Among the numerous articles of general military interest may be mentioned those entitled "Aufgebot," "Aufnahmen and Aushebung," while some special technical subjects will be found discussed under such titles as "Bajonettangriff," "Attacke," and "Batteriedeckungsbau," which last is most admirably illustrated. Among the naval articles of more than passing mention are those under the headings "Artilleristische Maschinen der Kriegsschiffe," "Atlantischer Ozean," "Ausstossrohr," "Azimut," "Babcock und Wilcoxkessel." Military hospitals and military sanitation are ably discussed under the titles "Arznei- und Verbandmittelversorgung," "Aerztliche Fortbildung," "Atmung," "Augenkrankheiten," "Bakteriologie," and "Baracken." A very clear presentation of military and legal relations, in other words, the subject of military jurisprudence, will be found under the titles "Ausland" and "Auswanderung." For the first time we find an exhaustive review of the historical development and the military value of expositions.

My System. Fifteen Minutes' Work a Day for Health's Sake. By J. P. Müller, ex Lieut. of Engineers, Klampenborg, Denmark. With forty-four illustrations and a time-table. Translated from the fifth edition of the Danish original. New York: G. E. Stechert & Co. Price, in colored paper covers, 75 cents net; red cloth, gold lettering, $1 net.

Müller's book "My System" has become almost a household word in Germany. Indeed, it is referred to in more than one German comic journal with humorous approval, as well as in such literary works as Andrejev's "Geschichte von den sieben Gehenkten." The system described is an excellent arrangement of gymnastic exercises intended to consume not more than fifteen minutes a day and yet to develop the physique. There can be no doubt that if the suggestions of this book are carried out, a weak body can be scientifically built up.

A New Light on Ancient Egypt. By G. Maspero. New York: D. Appleton & Co., 1909. 8vo., 315 pp. Price, $[illegible] net.

Prof. Maspero is one of the [illegible] Egyptologists in the world and he states in his Preface that he has been fifteen years trying to bring a science, supposed to be comprehensible only to experts, within the reach of the ordinary man, and it is gratifying to find that the [illegible]

[illegible] been wasted. He has drawn his material from everything that can be discussed with educated people, without demanding anything more than a little attention. Excavations, religion, travels, popular customs, literature, and history have each and all furnished him with subjects. The result is a living picture of the researches made in the domain of Egyptology during a period of fifteen years. The book is a most fascinating one to all who have even a slight appreciation of what Egyptology really means. Many chapters deal with the very latest discoveries and matter that has never before appeared in book form.

The Life of Major-General Sir Charles William Wilson Royal Engineers, K.C.B., K.C.M.G., F.R.S., D.C.L., LL.D., M.E. By Colonel Sir Charles N Watson. New York: E. P. Dutton & Co., 1909. 8vo., 419 pp. Price, $5.

The material from which this memoir of the late Sir Charles Wilson has been compiled consists principally of his own diaries and notebooks, which he always kept in a very thorough manner; all his official reports printed in Parliamentary papers and all other public writings, and more especially, all his letters to his wife, which recorded everything which he did and saw during his travels. Sir Charles Wilson's career was a remarkably varied and interesting one. He was selected to serve on the North American Boundary Commission. For many years he served upon the Astronomical Survey, and had charge of that department in Scotland, Ireland, and afterward in the United Kingdom. He also was employed by the War Office Foreign Office Survey under Lord Dufferin in Egypt. Sir Charles was prominent in his close connection with the Soudan question and the mission of Gen Gordon. In the Nile Expedition of 1884 he held the important position of Chief of the Intelligence Department. Sir Charles Wilson had many interests in life outside of his military and political positions and probably did more than any other man to increase the knowledge of the geography and archæology of Asia Minor, Palestine and adjacent countries. The book is an entertaining one to those who care for memoirs.

Stained Glass Windows in England. By Charles Hitchcock Shirrel. New York: J. Lane Company, 1909. 12mo., 254 pp. Price, $2.50 net.

This admirable book is a rational guide to the study of stained glass in England. It is accompanied by maps which show how the cities may be visited in their proper sequence with as little fatigue and crossing of one's path as possible. Not only are many noble cathedrals visited but smaller religious edifices and secular buildings of many types are treated. In this latter category are treated the universities of Oxford and Cambridge and one of the finest of the stately homes of England—Knole. Any cultivated person who completes the tour as outlined will have obtained a well rounded impression not only of glass but also of history, as well as an intelligent insight of the customs of England. Unfortunately no form of illustration can hope to reproduce the combination of light and color which makes up the beauty of stained glass. Those selected by this book are the best obtainable, but are chiefly useful in showing how the windows are set. It is not a technical book, so that scale drawings are not required. It is a beautifully printed and bound book.

Happy Hawkins. By Robert Alexander Wason. Boston: Small, Maynard & Co., 1909. 16mo., 352 pp. Price, $1.50.

"Happy Hawkins" is a quick-tempered, independent, loyal, lovable, adventurous, and philosophical cowboy of the plains. He tells his own story in his own way, and after a plan of his own. His knowledge of human nature, his simple-hearted devotion to those he loves, his ability to get into trouble and out of it, his self-possession in any society—all these qualities make him one of the most original characters in modern fiction. Mr. Wason tells a story full of red blood, with action, romance and the interplay of hot human passions with an intricate plot, an abundance of incident, a great variety of scene and type, shrewd philosophy, genuine pathos, and, perhaps best of all, real fun and humor on nearly every page. It covers the growth from childhood to womanhood of Happy's little playmate, Barbara, the daughter of his employer "Cast Steel" Judson, of the Diamond Dot ranch and swings round from Wyoming to Texas, Nevada, California, Montana, and back again. The book easily establishes the author's reputation as a great story teller and fun maker.

Legal Notices

PATENTS

INVENTORS are invited to communicate with **Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C.,** in regard to securing valid patent protection for their inventions. **Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.**

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our **Hand-Book** on Patents will be sent free on request.

Ours is the **Oldest** agency for securing patents; it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office 625 F St., Washington D. C.

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending August 24, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Adding machine, J. G. Vincent	[illegible]
[illegible]	[illegible]
[illegible] for carbureting, A. L. Lewis	[illegible]
Alkali silicates manufacture of soluble B B. Weissmuller	932,804
Alum, making iron free B Strohbach	932,067
Ammunition rammer J. Becker	932,004
Amusement apparatus, P B. Haight	931 963
Amusement apparatus, J W Armitage	932,099
Amusement device Potts & Lovell	932 057
Anchor, W F Kenney	932 307
Animal antirooting device L J Owen	931 794
Ash can and other or similar receptacle T E Diamond	931,918
Automobile, U S Snyder	931 893
Automobile combination lock M L. Yoster	931 981
Automobile foot warming radiator E M Field, Jr	932 118
Automobile wind shield H F Holbrook	932 120
Awning H. Smith	931 967
Axle cutter adjustable O J L. Byers	931 729
Bag, Renney & McAnulty	931 895, 931,897
Bag holder G L. Lyon	932 151
Baggage rack W S Hamm	932 121
Baking powder, J H Kellogg	932 138
Baling press, J S. Peightel	932,016
Ball players armor base W J Sullivan	932 052
Bandeau W L. Manchester	932 304
Barrette E B. Kingman	931 877
Basket rack G. L. Walters	932 190
Battery. See Secondary battery	
Battery cells, gas controlling apparatus for O D Apple	932,067
Bearing ball, H La Casse	932 144
Bearing retaining collar and cup ball W R Clarkson	932 247
Bearing roller A T Killian	931 931
Bed and davenport combined A F Finglerth	931 852
Bed attachment H L. Appleton	932 216
Bed disappearing J Rountree	931 982
Bed joint metal J M Adams	932 217
Bed swinging couch J Lappin	931 790
Beds invalid's foot rest for M Weld	931 908
Bedsteads folding clothes rack attachment for F D Pelletier	932 109
Beer and other liquids, apparatus for carbonating and dispensing E B Mower	932 048
Beer cooler K T Schutzinger	931 891
Belt conveyer, H E. Heaton	932 015
Belt shifter J Cressman	932 000
Beverage dispensing system A D Jones, 932 284	932 285
Bicycle frame cushioning O J Laravie	931 932
Bill fold, S. L. Wentz	932,208
Binder file loose leaf book etc temporary J Walker Jr	931 810
Binder or loose sheet holder temporary G H Renworth	932 059
Blacking box J F Pinson	932,171
Blind E A Foster	932 203
Block forming machine G L. Langer	932 135
Boats, entrance shaft for submarine, R d'Equevilley Montjustin	932 179
Boiler C Wegener	931 907
Boiler arches, rib for E. W Ashenden	931 834
Boiler flue cleaner J Wiechmann	932 209
Boiler furnace, steam W G Munson	931 962
Boilers, interior arrangement for smoke boxes of tubular F W Born	931 727
Bolt mechanism door Furman & Howe	932 383
Book binder loose leaf C O Van Buren	931 816
Book holder A F Stone Jr	932 148
Book loose leaf Page & Hedges	931 799
Book, manifolding Auscher & Debainault	932 105
Boot and shoe straps, machine for covering L A Gale	931 748
Boring tool holder Ennis & Selam	932 178
Bottle bracket, J W Barnard	932 086
Bottle filling device L Whitton	932 162
Bottle for teething liquids and other liquids or materials G J Packe	931 796
Bottle holder E W Houston	932 128
Bottle holder nursing C Starhard	932 344
Bottle non refillable M A Griffin	932 422
Bottle washing machine Utard & Gimonet	932 193
Bottles or like articles machine for cleaning, G R. Lawrence	932,145
Bottling apparatus, liquid, F G Riley	932 415
Brake applying mechanism automatic F A Pierce	931 799
Breech closure M Hermsdorf	932 017
Bridge lift Waddell & Harrington	932,150
Brominated beta naphthylindigo, Schmidt & Voss	932 384
Brush holder A L. McHugh	932 309
Buckle garment M Rubin	931 802
Buckle trace-supporting back band D Jacks	932 388
Buckles, coin holder for belt J C Waugh	931 823
Building block and wall A R. Matthews	932 157
Building construction E D Martin	931 943
Building frame anchorage and weatherproofing, O J Appleton	931,714
Burglar alarm, A Verbaeven	932 308
Butter molding and printing machine F Mellish	932 049
Cable clamp, W H Kempton	931 930
Cable retaining mechanism for overhead carrier yokes and riders, W Gutenkunst	931 860
Cable switch mechanism, overhead carrier W Gutenkunst	931,861
Caddy grower's G A Schmid	932 062
Calculating machine, Dreyfus & Levy	932 255
Caliper gage E F Hathaway	931 759
Camera, A L. Richardson	932,336
Camera, photographic C E Hutchings	932,302
Can lock, milk J Varoga	932 194
Cans, manufacture of sheet metal, R H Smith	932 141
Car coupling device J W & W W Howard	931 937
Car door grain C S. Eaton	931 739
Car door grain, F. J A Schnoor	932 335
Car dumping A Becker	931 730
Car, dumping, T Lawson	931 983
Car lighting system, E C Folsom	932 114
Car roof E V Doeelson	931 798
Car sheathing, L C. Bassford	932 367
Car street, C O Birney	931 724
Car window cleaning device G W McKee	932 061
Cars, step-operated circuit breaker for electric, R. B Herron	932 012
Carbonating apparatus, C L. Bastian	932 008
Carbureter F J Watt	932,360
Carcass handling apparatus, W B. Farris	931 744
Cards, playing A H Wheeler	931 977
Carriers, direct movement lock and trip mechanism for W Gutenkunst	931,859
Cartridge magazine pocket for self loading rifles, L P Kennedy	931 763
Case. See Shot case	
Caster, W. Muler	932,098
Caster ball, H M Powers	931 958
Casting machine mold, Mohr & Gerwig	932 047
Castings, device for forming molds to produce screw-threaded, O A. Hattersley	931 760
Castings, mold for making I-beam, E De la [illegible]	932,030
Cement and making same, waterproof Portland, C. McCormick	931,894
Cement, making Portland, J M Carrere	932 074
Cement pipe machine, W J. Jeffries	932 123
Cementitious compound and producing the same fixed color A C. Horn	932 280
Chain, articulated, J. Krone	932 184
Chart for dressmaking adjustable R. A Terry	931 866
Chuck Fegley & Leopold	932,259
Churn J S Harris	932,274
Cider press and separator F H Brets	931 728
Circuits, means for protecting operators ringing leads from short W W Dean	932,003
Cloth cutting and folding machine C N Culpitts	931 996
Clothes drier W C Davids	931 917
Clothes drying device, J M Teach	932,353
Clothes stick J R. Hays	932,276
Clutch A O Mather	932,185
Clutch friction A L. Smith	932 340
Clutch friction G E Titcomb	932 356
Coaster G Looney	932 303
Coaster and brake device A P Morrow	931 787
Coat hanger I. Trestman	932 357
Cock, M Strelesky	932 188
Cock or faucet water Porter & Binnington	932,172
Coin controlled apparatus, G A Long 932,036, 932,403	932,404
Collar horse G W Hahn	931 862
Comb lock slide and back W C Bridges	931 841
Comb protector J A Kennedy	932 027
Combination wrench J O Johnson	932 130
Commutator leads support for F Mattman	932 042
Compound of the anthracene series and making same F Kacer	932 290
Concrete article, ornamented molded G H Bartlett	932 002
Concrete pipes machine for making J Thomas	931 973
Concrete sleepers block for receiving rail fixing devices in reinforced Clebeaux & Hennebique	932 300
Condensing system Woolf & Rafferty	932 220
Controller time limit device H W Cheney	931 864
Conveying apparatus W M Shaw	931 892
Cooker and processer, agitating J Jennings reissue	13 015
Cooking apparatus, J Truman	931 814
Coop brooding P G Townsend	931 974
Corset clasp, M Wallstein	931 820
Cotton gin W M Rhein	931 801
Cotton etc machine for compressing W M Holmes	931 762
Cotton pickers, suction head for vacuum J S Thurman	932 068
Cotton press A H Thomas	932,364
Counting machine mechanical F W Russell et al	932 331
Crate collapsible H W McComas	931 964
Crate folding S E. Smith	931 909
Cup holding rack, A. Insinger	932 021
Curtain bracket M. Wheeler	932 078
Curtain fixture F A Newton	931 780
Curtain fixture J Darling	932 282
Curtain pole support and curtain shade roller bracket combined H E. McCoy	932,308
Cushioned wheel W H Bachtel	931 717
Cuspidor carrier A J Fasenmyer	932,258
Cuspidor sanitary D R Reefe	932 174
Cutter head J F Stedman	932 343
Cycles etc rigid wallet for R. Marguerittas	931 782
Deflocculating non metallic amorphous bodies, E G Acheson	931 832
Dirt remover J F Workman	932,227
Disinfecting apparatus, J H Van Dyne	931 817
Dispensing apparatus, B. M Martin	931 851
Display rack for curtains F Hansen	932 387
Distribution system, H L. Van Valkenburg	932 073
Ditching machine J W Humphreys	931 763
Door bolt multiple T F Rotchford	932 330
Door fastener barn W F Jones	932,288
Door fastener sliding C W Storandt	931 885
Door hanger truck frame T C Prouty	931 709
Door lock hotel A Arens	932,304
Draft equalizer A Hines	931 925
Draft gear combined spring and friction W D Wilcox	932 215
Draft hook G Snell	932,416
Draft rigging friction C J Nash	931 955
Drying apparatus A Roley	932 106
Drill bit swaging and sharpening machine fluid controlled J G Leyner	931 770
Drilling machine C B Richards	932 000
Dust pan I B Hawkinson	931 867
Dye and making same Julius & Blangey	932 289
Dye and making yellow E. Fussenegger	932 296
Ear protector G C Kirkpatrick	931 708
Earth scraping apparatus H G Ward	932 075
Eaves trough L H Dickman	932 254
Egg beater B Kreuzberger	932 204

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

$6 PER DAY PAID to competent automobile drivers A complete instruction book that will qualify you for these positions will be sent postpaid for 25c. This book tells all about driving and adjusting automobiles, explains all gasoline and automobile troubles. Satisfaction guaranteed or money refunded. Address George N Pearson Dept. 8 Bala, Pa.

Inquiry No. 8888.—Wanted to buy nickeloid for buttons.

WILL GIVE AN INTEREST in a vending machine to parties who will pay for models. Address P O. Petersen Box 172, Perth Amboy N J

Inquiry No. 8918. For manufacturers of "Wyatt's Electro Catalytic Sparking Plug."

PATENTS FOR SALE

FOR SALE.—Patent No. [illegible] Metal shelf with folding brackets, as illustrated in Scientific American of August 28, 1909. Now being manufactured and marketed in New York and surrounding States with good results. Rights to distant States can be obtained by responsible manufacturers by applying to The Dahl Mfg. Co. 38 W 14th Street, New York.

Inquiry No. 8931 For the manufacturers of silk paper

FOR SALE.—Patent No. [illegible], rowing appliance; works perfectly every boatman needs a pair Make us an offer James & Deacon Velasco, Texas.

MISCELLANEOUS

HAIR GROWS when our Vacuum Cap is used a few minutes daily Sent on 60 days' free trial at our expense. No drugs or electricity Stops falling hair Cures dandruff Postal brings illustrated booklet Modern Vacuum Cap Co., 586 Barclay Block, Denver Colo.

Inquiry No. 8938.—Wanted the address of Worthington Boiler Co.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates Small and special lists compiled to order at various prices Estimates should be obtained in advance Address Munn & Co. Inc. List Department, Box 773, New York

Inquiry No. 8931 For parties who manufacture the Western Stump Borer for boring stumps.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc. List Department Box 773, New York

Inquiry No. 8941.—For manufacturers of machinery for making fly screens.

Inquiry No. 8960.—For the address of the Windsor Mfg Co. manufacturers of waterproof collars and cuffs

Inquiry No. 8966.—Wanted the address of the Columbia Motor Co.

Inquiry No. 8969.—Wanted machines that make accordion dress plaiting (steam)

Inquiry No. 8977. For manufacturers of machinery for manufacturing denatured alcohol.

Inquiry No. 8980.—For the address of manufacturers of mortars and pestles that are used by druggists.

Inquiry No. 8981. Wanted the address of the manufacturers of Cypress wash tubs.

Inquiry No. 8987. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

Inquiry No. 8996. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

Inquiry No. 8997. Wanted the address of the manufacturers of bread or cake boxes.

Inquiry No. 9001. For the address of progressive manufacturers of fruit jars.

Inquiry No. 9007.—Wanted a tin churn for churning milk that has a wire spring at top and bottom of churn and operated by pressing the wire springs.

Inquiry No. 9009.—Wanted the address of the manufacturer of the "Leech" showcard holder, a device which is held to the outside of a show window by rubber cups

Inquiry No. 9010. Wanted to buy a "Rector Help-a-Phone."

Inquiry No. 9011. For the manufacturers of a patent sewing needle that is made to slip over the thread; the eye is split so as to open and receive the thread.

Inquiry No. 9012. Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

Inquiry No. 9014.—For manufacturers of machinery supplies etc to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

Inquiry No. 9015. Wanted the address of the manufacturers of a solid link chain made without welding made in brass, several different sizes, made on an automatic machine

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

Inquiry No. 9017.—Wanted the address of manufacturers or dealers in card board plaster or wood pulp for plastering.

Inquiry No. 9018. Wanted the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9019.—Wanted address of The Old Town Canoe Co.

Inquiry No. 9020.—Wanted the addresses of the manufacturers of metal novelties.

If Abraham Lincoln Lived To-day He Would be a Reader of "Success Magazine"

Because it works for what he wrought for, and strives for what he fought for—emancipation, freedom—the larger emancipation of the mind, the freedom that comes by knowledge of the truth.

We know the homes to which Success Magazine ' is welcomed We know the classes of people, and the kind of people who read it people of pronounced patriotism not the patriotism of the politician but the patriotism that is pure love of country—passionate reverence for the country's far flung flag

You can understand from this that Success Magazine is **different, radically different,** from other magazines It is different as Lincoln was different from other men It is different in aims, ideals and purpose It incites to optimism high thinking and pure living It makes appeal to the men and women who are the back bone of the nation the stalwart Americans who without the inflexible Puritan rigidity preserve the Puritan integrity which was the foundation of the Republic s greatness

Radically Different Advertising

There is another way in which "Success Magazine" is different, radically different—its advertising pages are edited to keep pace with its literary and moral ideals.

This means that every month there is a *sacrifice of thousands of dollars* to keep the advertising pages above suspicion, by excluding pernicious advertisements and admitting only advertisements of reliable goods honorably presented and honestly sold

This explains why Success Magazine is able to *guarantee its advertisements* to every subscriber of record—over 200 000—and protects these subscribers from loss by any advertisement appearing in its columns It explains why Success Magazine advertisers get returns which in proportion to circulation are not approximated by any other publication

Why YOU Need "Success Magazine"

The greater your success in creating a happy American home, the greater your need of the stimulating, uplifting influence of "Success Magazine "

It deals with the work and play the joys and sorrows of American men and women—in the home the community the nation It is the magazine that clipped Speaker Cannon s wings that first exposed the indecent stage that ran the financial fakirs into the cyclone cellars that is stirring the Church to look our religious problems in the face that in a word reflects the all important interesting sides of American life It prints the frankest strongest articles and the liveliest fiction

It gives all the significant news of the world each month packed into a nutshell for quick easy reading It prints monthly a chuckling bubbling page of short funny stories verses and anecdotes for which it pays ten cents a word to contributors to you It carefully advises men and women in the ticklish matter of investing their savings

It prints monthly Orison Swett Marden s talks on character building men and women building He writes for no other magazine

HONOR TO WHOM HONOR IS DUE

Within the last two weeks announcement has been made of one of the most romantic and interesting achievements connected with the history of exploration since the day of Columbus. The announcement of the discovery of the North Pole was one which fired the imagination of the most torpid and stimulated the enthusiasm not only of scientific men, but the whole civilized world.

The knowledge that this elusive goal, which has baffled the energies of man for so many generations, had at last been reached, naturally led to universal rejoicings and much national pride.

Within a few days the announcement of this discovery was followed by news that another American explorer had reached the same goal.

This natural feeling of exultation was, however, quickly dimmed by the criticisms and accusations which followed the first cable dispatches, which made it patent to all that the claim of one of the explorers was to be disputed by his rival, and that the public was to be treated to a long drawn-out and tiresome controversy.

It is unfortunate that the daily press, in its eagerness for news items and for copy controversial and sensational in character, should have seized upon these exceptional circumstances, with a view of fomenting a bad feeling which was regretted by all, and that in many cases, it should have taken sides, not with the view so much of reaching the truth as to become partisans in a controversy, with a view of stimulating circulation and private gain. This deplorable attitude is not confined to this country, as the same journalistic policy is noticeable in the foreign press. This is a mere condition of the times.

The truth in regard to both these explorations must and will be known. Honor must be given where it belongs.

It is a somewhat unusual precedent to doubt the statements of discoverers, especially when they had been connected with any particular line of exploration for a period of many years. It is most fortunate, however, that the two parties to the controversy should both be Americans, and that there is no danger of the dispute assuming an international aspect.

Those who are in a position to judge of these matters—the scientific men who have interviewed the explorers—are many of them of the opinion, at the time we are going to press, that the description of the exploration of Commander Peary tends to confirm the conditions as described by Dr. Cook.

Of all fields of human endeavor, there is none to which the world has been ready to accord greater respect than that of geographical research, and, because of the multiplied dangers and hardships of Arctic travel, the men who have pushed out farthest in the quest of the North Pole have been especially favored with national attention and municipal honors.

With a unanimity out of all proportion to the results to be obtained, it has come to be recognized that the most valued prize of the few that remained to be won by the explorer was reserved for him who should first set his foot upon that point which forms the northern extremity of the earth's axis. With the slow passage of the centuries, each bearing away its roll of men who have sacrificed their lives in the effort to solve the secrets that lie within the Arctic Circle, the quest for the North Pole had come to take on, moreover, a certain color of romance which detracted nothing from its dignity as a serious scientific problem, and the record of unwearied patience, heroic courage and sublime self-sacrifice which has marked these centuries of polar exploration, has served to place both the men and their mission upon a very high plane of human regard.

Therefore we look upon it as most regrettable that the almost simultaneous announcement by two American explorers that they had reached the North Pole should have set on foot an undignified controversy of world-wide notoriety. For here we have no mere difference of opinion between two private individuals. One of the disputants, at least, by virtue of the fact of his bearing a high commission in his country's service, and each of them as having but recently planted the flag of his country at the very peak of the world, must necessarily speak and act as a distinguished representative, for the time being, of his native land. Whatever of disappointment, or of fancied or actual wrong, may have been felt by the sender of that accusing dispatch from Labrador, consideration of the dignity of the navy and the nation should have sealed his lips.

REPORT OF THE CHIEF OF ORDNANCE.

For the average civilian, the most interesting section of the last report of the Chief of Ordnance of the United States army will be that which deals with the new 14-inch gun, which for the future will constitute the principal weapon in our scheme of coast defense. Of the five guns of this type provided for by Congress, four are to be built of concentric cylinders assembled by shrinkage in accordance with the system heretofore in use, and the fifth is to be of the wire-wound type. The manufacture of two built-up and one wire-wound gun is well under way, and the construction of the other two built-up guns will be undertaken as soon as the forgings can be procured.

The motive for the design of the 14-inch gun was the desire to produce a weapon that would not be subject to the destructive erosion of the bore that characterizes the present 12-inch guns of high velocity, which is so severe that the 12-inch piece, with a muzzle velocity of about 2,500 feet per second, is so badly worn away in the rifling after firing less than 100 rounds that the projectile fails to bite on the rifling and leaves the muzzle of the gun with insufficient speed of rotation. As a consequence the axis of the projectile fails to remain true to the line of flight, or trajectory, and the projectile itself begins to turn end over end and fails to strike the target head on. The rapid wear of the interior of the bore is supposed to be due to the extremely high temperature which accompanies the high powder pressures that are necessary to give high velocity. Since the striking energy of a projectile is equal to the product of its weight and the square of its velocity, it is possible, by increasing the weight of the projectile, to decrease the velocity without a loss of striking energy. This is what has been done in the case of the 14-inch gun, which, as compared with the 12-inch gun firing a 1,000-pound shell at 2,500 feet per second, will fire a 1,600-pound shell at about 2,100 feet per second and with a much lower powder pressure and temperature. The decrease in the erosion is expected to give the 14-inch gun more than double the accuracy life of the 12-inch gun.

The report tells us that in the design of the 14-inch gun the question has arisen as to which of the two methods of construction gives the longer life to the gun, the use of a relatively large or of a relatively small powder chamber and propelling charge. Under the former set of conditions the maximum pressure corresponding to the prescribed muzzle velocity will be appreciably less than under the latter conditions, but the powder charge will be correspondingly greater, and experience has indicated that erosion is affected not only by the maximum pressure of the powder gases but also by the weight of the propelling charge in guns of the same caliber. To determine which method to follow, tests have been made of two 3.5-inch guns, whose ballistic data are exactly similar to those proposed for the 14-inch guns, in accordance with the two systems above described. These firings will be continued until it has been definitely ascertained under which of the two sets of conditions the accuracy life of the gun is the longer.

A new 6-inch, wire-wrapped rifle, with ballistics identical with the 6-inch rifle of the model of 1897, is to be built, in which the use of a superior quality of steel in the tube and the substitution of a wire envelope for the steel jacket will not only greatly increase the elastic strength of the gun but will reduce the weight about 25 per cent and will somewhat reduce the cost. A new design for a 12-inch wire-wrapped mortar, of the same power but weighing 20 per cent less than the 12-inch mortars now in our fortifications, has recently been completed. The question of erosion is the most serious one confronting the Board of Ordnance. Extensive tests with the 0.30-caliber rifle have shown very clearly that the erosion is three or four times as rapid with a propelling charge of nitroglycerin powder as with one of nitrocellulose powder, and that the temperature has a great deal to do with the erosion. [illegible] temperature of combustion [illegible] [illegible] deg. C., that [illegible] only about 2,300 deg. C. It is [illegible] that, if it were practicable to so modify the [illegible] tion of our smokeless powders as to reduce the temperature of combustion, erosion would become a much less serious factor. Here is a problem for the chemist, the solution of which would win for him one of the richest prizes in all the history of military and naval inventions.

Experiments have been carried on with the object of extending the accuracy life of cannon by the use of a rotating band on the projectile, considerably wider than that now employed. We gather from the report that the ordnance experts expect that the wider band will merely insure better rotation of the projectile when the rifling is worn, but that they do not anticipate that it will prevent erosion.

The SCIENTIFIC AMERICAN has for many years been of the opinion that erosion is largely due to the abrading effect of the rush of gases at high velocity past the projectile, and that if this were prevented by a more perfect obturation, or closing up of all interstices between the shell and the gun, the erosion would be greatly, if not altogether, eliminated. Although the report makes no mention of the fact, we understand that experiments with a new form of rifling band acting in conjunction with a packing material at the base of the shell, have shown most encouraging results, regarding which we hope to give further information at a later date.

THE COMPOSITION OF THE UPPER ATMOSPHERE.

The composition of the air at great altitudes has long attracted the interest of meteorologists. In the earliest ascensions of unmanned registering balloons, twelve or fourteen years ago, attempts were made to secure specimens of air from the upper strata of the atmosphere. In one case half a gallon of air was thus collected. Its analysis showed a composition identical with that of air near the earth's surface. The system of monthly ascensions which was subsequently instituted revealed the remarkable phenomenon of the "permanent inversion layer." The diminution of temperature with increase of elevation, which was observed at all lower levels, was found to cease at a height of about 10,000 meters (32,000 feet), above which level the temperature was found to rise, slightly but regularly, with increase of elevation. This upper warm stratum has been found everywhere, in the tropical and temperate zones, near the Arctic circle, and over the Atlantic Ocean.

The discovery of this singular reversal of the temperature gradient suggested a possible difference in the composition of the atmosphere at high and low levels. The French meteorologist Teisserenc de Bort, although he did not share this opinion, undertook an experimental investigation of the subject. He suspended from a sounding balloon a glass tube closed at both ends and with one end drawn out to a fine point, which was sealed in a flame after the tube had been completely emptied of air. At a certain height an electrically driven hammer broke off the fine end of the tube and admitted air. The tube was then sealed again by the heating of a platinum wire by current from a small storage battery. The electrical contacts required to effect these operations were made either by the barometer at a prescribed elevation or by the clockwork of the meteorograph. The glass tube was suspended at a distance below the balloon which prevented the entrance of a trace of escaping hydrogen.

In this way specimens of air were collected at various heights in July, 1907. Another series of experiments was made on the Atlantic Ocean from the "Otaria," but the salt contained in the sea air made the electrical contacts unreliable.

The specimens collected were too small for ordinary chemical analysis, but they were tested, by special methods, for argon, neon, and helium. Argon and neon were found at all heights, from 26,000 to 46,000 feet. The characteristic yellow line of helium appeared in the spectrum of most of the specimens, but no trace of helium was found at the highest level (46,000 feet).

* * *

For the year 1911 there is being organized in Italy, under the patronage of King Victor Emmanuel, a celebration in honor of Amadeo Avogadro, this being the centenary of the publication of his celebrated memoir concerning the molecular state of gases and the well-known law which bears his name as to the change of volume of gases with temperature. His researches laid the foundation for chemical as well as physical theory. A committee has been formed under the direction of the Royal Academy of Sciences of Turin, and it is taking measures to publish a memorial volume containing his most important memoirs. Besides, there is to be erected a monument to Avogadro at Turin, in which city he was born and was professor of sciences. An appeal for funds is made to [illegible] are interested in the movement, the [illegible] headed by Senator S. Cannizzaro.

ENGINEERING.

The total length of railway under construction or [illegible] projected in India is 3,229 miles, of which [illegible] is by the British government and the rest by private companies. The estimated cost is over twenty million dollars

The replica of the "Half Moon" built to the plans of the late Heer C L Loder of the Dutch navy and recently brought over for the Hudson-Fulton Celebration, is now being rigged at the Brooklyn navy yard under the supervision of Heer E J Bentham, constructor in the royal navy who built her

The torpedo-boat destroyer "Flusser" built by the Bath Iron Works of Bath, Me for the U S navy, has recently completed the first of her official acceptance trials over the measured knot course off Rockland, Me The average of her five top-speed runs was 32 7 knots, while one run was made in 1 minute 46 4/5 seconds or at the rate of 38 7 miles an hour The latter is nearly three knots faster than the best speed of any boat in the American navy

The Montreux-Berne-Oberland electric railway in Switzerland has installed automatic gates at its grade crossings When the bow trolley of the car comes in contact with an auxiliary wire run close and parallel to the main trolley wire, the current passes through the auxiliary and operates a motor mounted on brackets on the iron gate post swinging down the gate and at the same time lighting lamps and ringing a bell. When the car has passed the gate automatically returns to the vertical position

The Panama Canal authorities have approved the purchase of a 20 inch pipe-line suction dredge made to order for use elsewhere by the Ellicott Machine Company of Baltimore but never used This is expected to be in use before the end of the present year on the hydraulic fill for the Gatun dam making the fourth suction dredger engaged in that work while a fifth will probably be added next year When the dam is nearly complete some of the dredges will be removed to the central division as the water in Gatun Lake rises sufficiently to permit dredging It is estimated that some 4 000 000 tons of material can be more economically removed than by steam shovels

Except for a few short distances totaling 127 miles automatic block signals now extend from the Atlantic to the Pacific Ocean According to the Railroad Age Gazette of the distance unprotected by this system 93,4 miles on the Southern Pacific in the Sierra Nevada Mountains uses the electric train staff The next longest gap 20 miles in length occurs where a change of line is about to be made The remaining gaps are due to bridges and points where changes are in progress. The line thus operated by the block system extends from Jersey City on the Atlantic to Oakland on the Pacific over a total distance of 3 245 miles and it includes the Lehigh Valley Railway to Buffalo the Lake Shore & Michigan Southern to Chicago, the Chicago & Northwestern to Council Bluffs the Union Pacific Railway to Ogden and the Southern Pacific Railway to Oakland.

A very remarkable demonstration of the possibilities of producer gas engines for small boats requiring less than 500 horse-power has recently been made by Mr H L Aldrich in a boat built for the purpose the results being described in International Marine Engineering for August The boat is 40 feet long over all 9 feet beam and 3 5 feet mean draft, and is driven by a four-cylinder four-stroke cycle engine of 35 horse-power and can cover between 800 and 900 miles at an average speed of 8 to 9 miles an hour on one ton of pea anthracite Such a plant can be conveniently and safely installed on coastwise schooners in the lumber and coal trades fishing and oyster boats and the like and in addition to the greater safety with anthracite at $4 a ton the cost of operation is about one-tenth that of a gasoline engine of equivalent power with gasoline at 15 cents a gallon

A train ferry service between Sassnitz in Germany and Trelleborg in Sweden has recently been opened conveying trains across 65 miles of open sea by means of which through train service from Berlin to Stockholm is now possible. The ferryboats two of which are owned by the German government and two by the Swedish State Railways are superior in size, speed and accommodations to any in the world and carry a full train of eight cars on two parallel tracks, the balance being maintained while loading and unloading by special trimming tanks. There is almost no tide at that part of the Baltic but the height of the water varies with the wind, so a double-jointed steel ferry bridge is provided, 160 feet long, with a large bolt in the seaward end fitting a hole in the stern of the ferry boat, to insure alignment of the tracks. When the cars are on the ferry, they are lashed down to the deck by special shackles, the car springs being relieved by screw jacks. Provision is also made for bracing them in heavy weather from the overhead girders of the vessel. The boats have complete and luxurious restaurants and sleeping accommodations for the passengers in addition to the car space.

ELECTRICITY.

Conversation by a wireless telephone, the invention of two lieutenants of the French navy is said to have been carried on between Toulon and Port Vendres, a distance of 155 miles

The electric process iron smelter at Herould on the Pitt River has recently delivered a carload of pig iron, produced by the electric process at $25 a ton—cheaper than it could be bought at tidewater It is pronounced to be of the finest quality for casting purposes.

The electric power station of the government buildings at Washington is nearing completion It is located in Garfield Park near the Capitol and connected with the legislative buildings by 7 000 feet of tunnels through which cables and steam pipes run The tunnels are large enough for a man to walk through comfortably so that breaks and other troubles can be quickly located and repaired

A transformer was short-circuited by lightning during a terrific storm at the village of Olginate near Lecco in northern Italy on August 18th subjecting the low pressure distribution system to a voltage of 9 000 Attempts to switch off the current by the residents alarmed by the blowing of fuses caused the death of several persons and a number of serious burns

At the Winnipeg meeting of the British Association for the Advancement of Science a model was exhibited by Mr S H Schneider which he claims will revolutionize the generation of electricity It consists of a collapsible airtight box which when closed sinks in water by its own weight On reaching the bottom it is expanded by a magnet when being lighter than the water displaced it rises to the surface where it again folds up and sinks The inventor states that a full sized generator ' weighing 600 000 pounds and displacing 10 000 cubic feet would generate 50 000 horse power at practically no cost of operation

Electric-car motormen in Berlin are subjected to three weeks training comprising 20 hours in the class-room and 40 on the cars in each week The course comprises the usual practice on a dummy platform and study of every detail of car equipment as well as sufficient instruction in overhead and track equipment to enable the motormen intelligently to report accidents After the recruit has completed the course he must pass separate examinations by the car engineer and the district traffic inspector Candidates receive half pay during instruction but to cover the cost of training each must deposit $16 which is refunded in full after one year s employment

Judgment has just been rendered in two suits of the Union Carbide Company against the American Carbide Company for infringements of the Willson product patent of 1895 and process patent of 1896 The patents are upheld as valid but no infringement is found Since the defendant company is exculpated of infringement partly on the ground that it manufactures carbide by means of what is strictly a resistance furnace and not an arc and the complainant company has also long relinquished the arc for resistance heating of the carbide materials it will be interesting to see what further steps are taken by the latter

The economical importance of maintaining uniform load factor is well shown by comparison of the records of the Appleton Minn Electric Company for last year and for 1905 prior to the installation of storage batteries. In the latter part of 1905 it was found desirable to maintain a 24 hour service but cost of continuous operation of the generating unit appeared to be prohibitive Chloride accumulators were therefore installed to store the surplus power when the plant was run at maximum capacity during the night and capable of giving out a third of that maximum for eight hours during the day The gross receipts of the company increased by 14 per cent in the following year in spite of which the fuel consumption for 1906 was actually less than for 1905 and making due allowance for interest and depreciation the net return on the storage battery investment was 14 per cent

The diary of a traveler from New York to Chicago by interurban trolley ' lines published in the Electric Railway Journal of August 28th shows that the limitation of electric-car lines to cities and suburban districts is a thing of the past and that such systems are no longer installed to supply purely local needs or to feed railways The first 115 miles was covered not strictly speaking on a trolley car although most of it could have been, but by the electrified New York Central Railroad to Hudson N Y as a matter of convenience Thence to Chicago all but 72 of the 1 143 miles was traveled on trolley lines in a running time of 45 hours and 34 minutes at a cost of $19 67 The author describes his journey as most pleasant and comfortable, revealing many attractive parts of the country unseen by the steam railway travelers and intends to repeat the trip finding that the running time can be reduced by over 10 hours.

SCIENCE.

Gréhant has studied the disturbances of respiration of various animals confined in an atmosphere in which acetylene was substituted for nitrogen the mixture containing 79 volumes of acetylene and 21 volumes of oxygen A pigeon died in 30 minutes a rabbit in 40 minutes while no effect was produced on a tortoise The respiration of frogs was arrested but when the asphyxiated frogs were brought into the open air they soon recovered their normal condition It appears from these experiments that acetylene is far less poisonous than carbon monoxide but it should be remembered that poisonous gases act very differently on different animals

In a recent number of the Scottish Geographical Magazine a claim is made on behalf of the British government to the island groups of South Georgia South Orkney South Shetland South Sandwich and Graham Land all in that part of the Antarctic continent nearest to America These islands are declared to be a dependency of the Falkland Islands Hereafter no whalers will be allowed to fish in those coastal waters or to make use of the harbors without buying an annual license at the Falkland Islands *This is the first serious attempt to take possession of* any considerable Antarctic area The Antarctic country is now the scene of a large reviving whaling trade

Time is a curious freak at the earth s poles and when Dr Cook says that he reached there at 7 o clock in the morning of Tuesday April 21st 1908 his statement is without certain meaning Presumably he carried Greenwich time in which tables for navigation are calculated So at the time of his discovery it was 2 in the morning at New York As this meridian runs to the North Pole as well as that of Greenwich its time also applies So does the time of every other meridian and in consequence at the same instant it was also 7 o clock Monday afternoon and every hour minute and second in between until 7 o clock Tuesday afternoon At both the North and the South Pole it is always two days at once and every day lasts for forty eight hours

The observed acceleration of the mean motion of Encke s comet was at first attributed to the effect of a resisting medium but subsequent changes in the comet s motion have made this hypothesis untenable Prof Hackenberg has made a preliminary research which appears to indicate that the observed changes may be produced by the action of dense swarms of large meteors Biela s comet is known to have been affected by a swarm or current of meteors which doubtless caused the division of the comet into two parts In 1906 Charlier published an elaborate investigation of the accelerations of the motions of comets which is in harmony with Hackenberg s theory Hackenberg promises soon to apply Charlier s results to the motion of Encke s comet

A German inventor Otto Nicolai claims to have invented a new method of welding aluminium using a specially prepared metal paste with different ingredients At a certain heat there is formed a mixture of aluminium oxide and the paste which gives rise to a chemical compound whose nature is not yet determined Excellent welding is obtained for the metal or nearly all of its alloys without any special precautions For aluminium bronzes such as are used for German torpedo manufacture which contain 90 per cent copper and 10 per cent aluminium it is required to add finely divided aluminium powder to the paste This latter must be used in all cases in presence of a great excess of the metal so as to form the above-mentioned compound to secure the proper welding He also solders aluminium to other metals such as copper iron nickel etc In this work he uses large pieces of metal or again thin sheet metal or wires with good results

More than once it has been asserted in good faith but erroneously that diamonds had been produced in blast furnaces In 1896 J Frank treated various products of the blast furnace with acids and obtained a residue composed of titanium cyano-nitride mixed with brilliant crystals all of which except one were very minute The crystals were not affected by mixed nitric and hydrofluoric acids which dissolved the titanium They showed no facets and were very fragile but as they were not attacked by any acid Frank assumed them to be diamonds Nothing further was heard of these crystals until recently when the subject was re-examined by Johannsen in the course of a study of the incrustations formed in two blast furnaces of which one had been in operation 14 years and the other 4 years Johannsen endeavored to obtain titanium cyano-nitride and he succeeded but found that compound mixed with fine sandy particles which were not attacked by hydrofluoric acid and were altogether similar to Frank s crystals But the particles refused to burn in oxygen fused to an opaque mass in the oxyhydrogen flame and dissolved completely in fused borax Analysis proved them to consist almost entirely of alumina.

AN AUTOMATIC ELECTRIC FOG-SIGNALING APPARATUS FOR RAILROADS.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

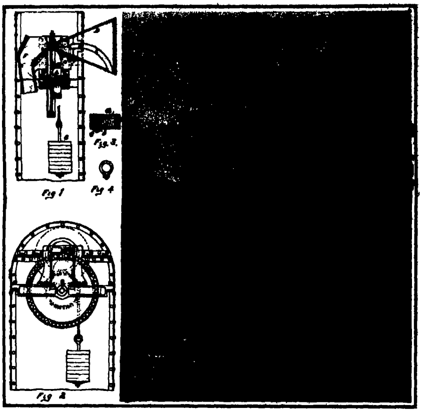
Interesting experiments have been carried out upon the Belgian State Railroads with a new system of signaling in fogs a system which is the invention of Mr W de Ruyter van Steveninck, a late officer of the Holland navy now resident in Brussels The important feature of this device is that it is absolutely automatic in its operation, the detonators being electrically fired by the train itself, and in such a manner that a powerful acoustic signal is given beside the track The signal is entirely independent of the operator though operative in conjunction with a visual signal, and always gives an adverse signal should there be any breakdown in any part of the apparatus.

The detonator signal is retained, because it affords the most striking and certain means of warning the crew of a passing train and cannot by any possibility be misunderstood An accident would therefore be directly attributable to willful negligence on the part of the engineer

The apparatus comprises a small waterproof pillar box mounted beside the track fitted with a trumpet facing the direction of the approaching train, this trumpet being placed on a level with the engineer in the cab of the locomotive. In this box is mounted a large wheel, provided with a peripheral magazine capable of holding fifty cartridges in grooved sockets. The forward action of this wheel is controlled by a pulley and counterweight, which is wound up like the weights of a clock and which will make one revolution of the wheel clockwise This wheel thrusts forward one cartridge at a time the cartridge being brought to rest in a small space in the neck of the trumpet by a spring buffer

The detonator (Figs. 3 and 4) comprises a cartridge case *a*, to the outside of which is screwed a small metal cap *b* In this cap is inserted a screw *c* insulated from the cap itself by a small tube of ebonite which tube also carries a short length of platinum wire, one end of which is soldered to the point of the screw and the other to the cap *b* which is filled with guncotton The cartridge itself is loaded with common black powder, and is closed at its outer end by a wad *f* The insulated screw in the cap is connected with one terminal of the battery and the cartridge cap itself with the other terminal the circuit being broken at the rail The approaching train as it passes the apparatus closes the circuit, either by means of rail contacts or a treadle placed in the track and immediately the circuit is established the platinum wire in the cartridge cap becomes incandescent and fires the guncotton, which in turn detonates the cartridge The sound of the explosion is deflected through the trumpet as well as the gases of ignition while the wad of the cartridge is blown to the ground through the curved tube *F* (Fig 1) Under the force of the recoil the cartridge case itself is ejected from its socket in the magazine wheel, and falls into a box (Fig. 1) whence it can be easily recovered Immediately after the explosion the magazine wheel, under the influence of the counterbalance weight commences to revolve bringing the next cartridge into the firing position in the neck of the trumpet, the extent of its travel being arrested by the buffer already mentioned, which insures its coming into the correct firing position This brings the apparatus into firing position again The empty cases can be collected and may be recharged, which serves to reduce the working cost of the system The rail contact can be placed either alongside the detonating apparatus or some distance in advance thereof according to the prevailing conditions Although the circuit is established and the detonation is produced as the front wheel of the engine passes over the contact, and the apparatus immediately resets itself, subsequent firing by each successive vehicle of the train is avoided by means of a relay, which cuts out the whole circuit until the last wheel of the train has passed completely by The relay then opens instantly, and sets everything in readiness for the next train. In this way useless expenditure of the cartridges is avoided, only one being fired for each train.

Should the line be clear, the apparatus is cut out of action, and no signal is given. A detonator is fired only when the signal arm is at danger, or when the signaling arrangement breaks down



AN AUTOMATIC FOG-SIGNALING APPARATUS FOR RAILROADS.

It is obvious that the apparatus may be set at some distance from the signaling operator's cabin, the occupant of which through not hearing the explosion, may not know whether the signal is fired or not. This event is ingeniously guarded against by means of an alarm to the operator's cabin, which gives indication that the explosion warning has been communicated to the engineer of the train Directly the detonator is fired a contact is closed and a circuit established with an electric alarm bell placed in the signal cabin This bell continues ringing until the operator acknowledges the intimation by breaking the bell circuit by the movement of a switch Similarly, intimation of the cartridge exhaustion of the magazine wheel is conveyed to the signal operator When the magazine has been so depleted that only five cartridges [illegible] the wheel, this alarm bell in the signal cabin commences ringing, and cannot be arrested until the apparatus is recharged. Should the operator ignore this warning, and the last cartridge be fired, the whole of the signaling arrangements are interrupted by locking the apparatus automatically, and their normal working cannot be restored and trains pass by until the apparatus is recharged with cartridges, unless the train engineer willfully ignores the stop signal.

The Belgian experiments, which were of a searching nature, conclusively established the efficiency and reliability of this ingenious system.

RAT DESTRUCTION BY ELECTRIC CURRENT.

Besides being harmful parasites, liable to work considerable damage wherever they take up their abode, rats are known to be the dangerous agents of propagation of infectious diseases, especially bubonic plague. Invading freely any vessel lying at anchor in harbors where that terrible scourge exists, they will carry contagion with them to any port touched by the ship, and accordingly present a most dreadful danger which it is hard to fight.

Many methods have, it is true, been suggested during the last few years for the destruction of rats, but none of these has proved free from serious drawbacks. "Smoking" by means of sulphurous acid gas is, for instance, liable to harm the cargo, while evicting the rats with illuminating gas is not free from some danger to the crew As it is, none of these methods lends itself to general use at any place infested by the fearful rodent.

A Viennese engineer, Herr von Florentin, Baron of Biederheim, has recently performed, in the presence of representatives of several administrative bodies, the Imperial Navy Office, etc., at the Charlottenburg Municipal Electricity Works, some interesting tests on an extremely original device, by which the rats (or any other vermin) are literally electrocuted.

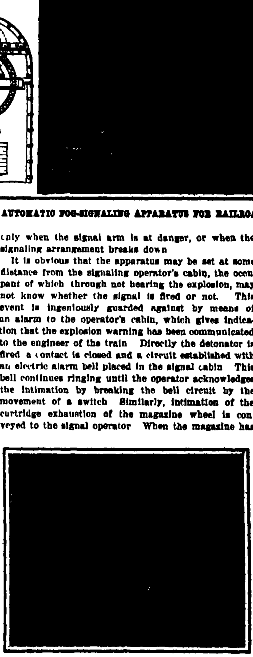
This patented apparatus takes advantage very ingeniously of all peculiarities of the rodent. Attracted by curiosity toward an electric lamp or by gluttony toward an appetising morsel, the animal itself closes the current bound to kill it in a maximum of 50 to 60 seconds. Access to the apparatus is always free, even after this has been filled with several electrocuted animals, and, as shown by experiment, no rat caught by the electric trap succeeds in escaping its fate.

One of the most interesting features of this scheme is that continuous, alternating, or three-phase currents of low tension, e g., 110 to 120 volts, are quite sufficient to electrocute the animals. Such currents are available at present nearly everywhere, and especially on board ship. Should no electric installation be available, it would be sufficient to provide a small accumulator battery, which in spite of its lower tension would produce quite similar effects.

The apparatus can be so arranged that the electrocuted animal itself signals its execution to any desired place, advising the watchman by an electric bell, or the lighting of a red incandescent lamp, that there are some killed animals to be removed The low tension of the current excludes any danger to men, and prevents any accidental electrocution of domestic animals.

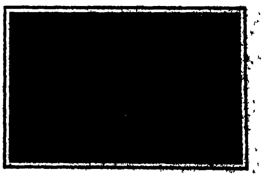
The photograph reproduced in Fig. 1 shows the moment the rat prepares itself to enter one of the pigeonholes of the apparatus. Fig. 2 represents the electric trap open, with an electrocuted rat.

This invention is exploited by a company in Charlottenburg.



Top view of trap with lid raised, showing electrocuted rat.

Entrance side of trap with rat about to enter.



Smaller form of trap with single entrance.

RAT DESTRUCTION BY ELECTRIC CURRENT.

H. A. Weersma has attempted a new determination of the solar apex, or the point toward which the sun and planets are moving. He finds, for the apex, the co-ordinates, right ascension 267.7 deg., declination +31.44 deg. The point thus defined is in the constellation Hercules, [illegible]

PORTABLE OUTLOOKS FOR ARTILLERY TRAINS.

BY DR. ALFRED GRADENWITZ.

A novel type of portable outlook for artillery trains has been recently designed by a German firm, the object being to allow men to note the effect of their own fire.

As shown in Fig. 1 the limber-pole of a field gun may be used as an observing station. The cartridges are carried in the limber case. The pole is hinged so that it can swing vertically. A special foot supports it on the ground.

Before erecting the pole a rope ladder with a shield is fixed in place. The rope ladder is tightened automatically as the pole is swung into position. The protective shield when not in use is carried in front on the gun limber arms and on the case frame and at the same time serves as a foot rest for the men seated on the limber. All the instruments used for observation are carried in receptacles below the foot rest as well as in the limber case itself.

The operator is equipped with a strap and hook by means of which he attaches himself to the pole. The rope ladder may be fitted at the top with an additional seat consisting of two rope ends and a transverse beam on which the operator may seat himself (see Fig 2). Instead of a rope ladder the pole may be provided with lateral rungs which when out of use are folded and received in recesses thus eliminating any risk of injuring the horses.

Fig 2 represents the limber of a 15 centimeter howitzer. The observing station is similar to the one shown in Fig 1 with the exception that it is made up of two poles fastened end to end.

In Fig 3 an ammunition caisson is represented for individually located field guns. These can be turned up so that the bottom constitutes the front of the shield. The armor is thicker in front than on the sides and roof. Below the bottom is located the box containing the observation ladder which is likewise armored. The ladder is of the telescopic type and can be extended and collapsed by means of a tackle. It is equipped with a top seat, telescope support and map table all foldable.

Fig 4 represents a three-section observation car. The observation ladder is swung up by means of a winch and tackle. Because of its height the ladder is held by guy wires. All the necessary instruments such as telephones etc are installed in the driver's box.

It may be said that observation wagons are by no means new. In fact they have been used as far back as in the fifteenth century for scaling the walls of fortresses. Later they were used in fighting fire and now we find them restored to their military dignity.

◆

Cinematophthalmia.

The illusion produced by the cinematograph is explained by the persistence of luminous impressions on the retina. The duration of the impression varies according to the intensity of illumination the frequency of interruption, and various other conditions. Its average value is 1/45 second. In order that the moving scene shall be reproduced in a lifelike manner before our eyes, the pictures must move before the lens and follow each other at intervals a little smaller than 1/45 second, so that one impression will remain when its successor arrives, and thus the pictures blend together, to a certain degree.

This series of rapid and brief excitations produces, in time, a certain fatigue of the eye and more or less [illegible] ocular troubles. A French physician, Dr Ginestous, has studied these troubles and given the name [illegible] to affections of this character. These troubles are fortunately not very serious. Dr Ginestous describes several forms. The first form is essentially temporary and consists chiefly in lachrymation and photophobia which compels the patient to close his eyes. The trouble begins with the passage of the first picture across the screen. In most cases the closure of the eyes for a few seconds is all that is required. The spectator appears to accustom himself and adapt his retina to the new task which is imposed upon it. In a second and more lasting form of the malady this retinal adaptation is impossible. As soon as the eyes are reopened the symptoms reappear. Some watering of the eyes and slight redness of the conjunctiva persist after leaving the hall but in most cases the symptoms rapidly disappear. In a third and still more prolonged type a true conjunctivitis persists for two three or four days. It is usually accompanied with redness, burning and itching lachrymation and photophobia but without agglutination of the eye lids. Finally in rare cases there are troubles of accommodation accompanied by headache and great difficulty in reading writing and seeing near objects.

Ophthalmias of this sort are not usually alarming. In most cases they heal rapidly even without any treatment and the most obstinate cases yield to very mild treatment. The best remedies are rest and mild eye-washes containing cocaine and adrenaline. The principal causes of the difficulty must be sought in the operation of the cinematograph.

I. Defects in sharpness of the pictures or in focusing the projecting apparatus make the seeing of moving pictures difficult and painful. The negatives should be as sharp as possible for the corresponding positives are magnified in projection to nearly one hundred thousand times their area and the defects of sharpness are magnified in the same proportion.

II. Place of the spectator. Charpentier has proved that the persistence of impressions on the retina depends upon the size of the retinal image and that the persistence is less for near than for distant objects. Consequently in a moving picture hall the seats nearest the screen are not the best.

III. Fatigue is caused by luminous impressions which are too strong or too weak. According to Charpentier's researches the persistence of luminous impressions diminishes as the illumination increases and conversely. This law is confirmed by the phenomena of moving pictures. Bright and strongly illuminated images are more fatiguing than others and most fatiguing of all is the abrupt transition from black to white or from dark to bright.

IV. According to the theory of the cinematograph it is necessary to produce a regular and rapid alternation of images and eclipses. In order to obtain these results the edges of the moving film are perforated with holes 4/5 inch apart into which mechanical fingers enter and thus regulate the movement of the film and hold it during the necessary period. But in time these perforations become worn and a certain amount of play results which causes vibration and blurring of the images. This fault apparently trivial is increased in direct proportion to the magnification of the projected image.

V. In order to prolong the spectacle some operators move their films with the minimum speed physiologically necessary to produce the persistence of the retinal images. Hence the eye is compelled to make an effort to retain and superpose the successive pictures and this effort necessarily causes retinal fatigue. The wearing of blue glasses has been recommended in order to avert these inconveniences. The director of the Pathé establishment at Bordeaux suggests moving the hand with the fingers separated so as to form a perforated screen before the eyes. Dr Ginestous rightly remarks that this device is not very practical.

The evil is not very great. It suffices to recognize its existence. Those persons whose eyes are fatigued by viewing moving pictures have always the recourse of giving up this form of amusement. There are many worse privations.—Cosmos.

Seeing by Telephone

To allow people conversing by telephone to see one another is known to be the ultimate goal of those inventors to whose labor we are indebted for the evolution of telephotographic apparatus. As the problem did not so far admit of any practical solution inventors have in fact been satisfied with transmitting by wire photographic pictures diagrams handwriting and the like. According to reports just received from Denmark a satisfactory solution is now offered. In fact two young Danes (the brothers Andersen) recently called at the offices of Politiken the well known Copenhagen daily in order to submit to the editor the principle of their idea particulars of which cannot yet be given out. Unlike the Korn apparatus optical transmission according to their scheme is not effected by means of any material sensitive to light such as selenium nor is a picture produced by photographic or mechanical means as in all the apparatus so far suggested. Transmission in fact takes place simultaneously so as to reproduce any objects situated at the sending station in their natural colors and motions their dimensions however being reduced.

The apparatus is connected by a contact with the telephone wire when the acoustic or optical [illegible] can be thrown alternately through the line. The operator is thus able at will to show himself or to

PORTABLE OUTLOOKS FOR ARTILLERY TRAINS.

bring before the eyes of the person at the other end any objects he may like to show him. As the apparatus, so far from being necessarily located immediately beside the telephone can be used within a considerable range provided the contact be obtained, the possibilities of this invention are obviously many Further details will be awaited with interest.

Fake Discoveries.

BY A. F KUMMERSON.

In the January, 1909 number of the Journal of Industrial and Engineering Chemistry appeared an editorial its contents being given here in part

The agitation against so-called patent medicines, which culminated in the National Food and Drug Act of 1907 also has served to awaken the public to the many deceptions which are being practised, and the many worthless preparations for general domestic use which are on the market The results of this movement have been first, to force a great many of the more palpable frauds to be withdrawn from the market, and second to provide for the correct labeling of all others, so that the purchaser may be in a position to buy intelligently Only those materials, however which may be classified under the head of food and drugs for the human system come within the scope of this legislation '

The writer mentions fake remedies offered in the market for the treatment of hard water for boilers and other products used in quantity in the industries He concludes with an appeal to the chemical profession to take measures to suppress these chemical fakes both by legislative and educational means. It is hard to see why people are so easily led into believing statements made in advertising literature even if indorsed by those in positions of importance who either out of ignorance or indifference have failed to investigate tests made in their presence before going on record as having witnessed them

Some years ago a sample of a chemical supposed to render wood fireproof was submitted to us for analysis A careful examination proved it to be common table salt for which a price of 25 cents a package (about one pound) was asked and undoubtedly was paid by scores of buyers We know of course that salt acts to a certain extent as a protection but by no means does it make wood fireproof and at the best it is worth less than 1 cent a pound Some time later two samples, one a pink and the other a blue chemical were submitted to us for examination A circular stated that the blue chemical added to gasoline would render it non-explosive the same was claimed for the pink chemical if added to kerosene or coal oil. The circular also contained a number of testimonials from persons whom one would expect should know better but undoubtedly they were not thinking deeply enough to consider what harm could grow out of their indorsement One of the testers, the chief of the fire department of one of our large eastern cities stated that in his presence the chemical was placed in a can containing gasoline the fluid being ignited in the can and poured into another containing gasoline without exploding either of them We wish to state that the oil termed gasoline is not explosive and if ignited in an open can will burn with a smoky flame so there was no merit in the material added It is entirely different if gasoline which has been kept in a partly empty can for some time is brought in contact with a lighted match or candle or if the can should be opened near a flame or light of any kind as an explosion will be the result of such carelessness. The explosion is due to the gases formed in the can and these mixed with air are highly explosive but nothing known at present will prevent this except precaution And if there were a remedy it would naturally have to destroy the qualities of the gasoline which make it valuable, that is its ability to vaporize rapidly and at a low temperature We made an analysis of both chemicals, which were offered at 50 cents a bottle containing less than an ounce of material and found them to be common table salt dyed the colors above mentioned What attracts the attention of the general public at present is a material supposed to make ashes burn It is sold and to our personal knowledge was bought, at very fancy prices We took the trouble to analyse a package and found that it contained powdered calcium carbide with 30 per cent of free lime and coal dust Whether these impurities were purposely mixed or their presence was due to an inferior grade of carbide we did not consider sufficiently important to investigate Any person of average intelligence ought to know that ash is a mineral admixture of coal and is non-combustible All statements made by careless investigators to the effect that the addition of any of these compounds to their coal increased the calorific or heating power are ridiculous, and the good results exist only in the imagination of the user The efficient way to obtain all the heating value contained in the fuel is to have proper grates and draft facilities, and to keep them clean Clinker and ash should be removed by frequent raking since too hard raking carries a large quantity of unburnt coal into the ash There are hundreds of other compounds of a similar nature, which flourish long enough to fill the pockets of the "discoverer," and we cannot caution the reader too emphatically to stop to consider the feasibility of a so-called discovery before buying it and recommending it without having seriously investigated its merits.

A Remarkable Nile Fish.

A very peculiar fish (*Tetrodon fahaka*), which is called "fahak" by the Arabs, is found in large numbers in the Nile at high water The fahak belongs to the group of globe fishes. In its normal condition it is ten or twelve inches long and of elongated shape. A thick mucus covers its entire body, with the exception of the abdomen, which bears numerous spines. The fish has a thick head, with a broad forehead and protruding eyes. The dorsal and anal fins are small, circular, and transparent, the caudal fin is larger, and of orange yellow color In general, the colors of the fahak are bright and harmonious. The back is very dark blue, the sides are striped blue and orange, the abdomen is yellow, and the throat snow white. The mouth is of peculiar shape, each jaw being divided in the middle, so as to produce the appearance of four large teeth, whence the name *Tetrodon*, meaning four-toothed

The most interesting peculiarity of the fahak is its power of inflating itself like a balloon, by drawing in a large quantity of air Usually it swims in the manner of other fishes, but when danger threatens it rises quickly to the surface of the water and begins to pump air into an extension of the gullet. By this means the abdomen of the fish soon becomes so greatly distended that it exceeds the rest of the body in size The fish loses its equilibrium, turns over and floats on its back, and at the same time the spines of the abdomen are erected By this transformation the fahak is protected against the attacks of its enemies. If one of these seizes it, the aggressor is wounded by the spines and thenceforth leaves the unpleasant creature alone If the inflated fish is grasped by the hand it endeavors to draw in still more air, as if it were well aware of the importance of this action to its safety When the danger is past, the air escapes with a slight hissing noise, and the fish gradually resumes its normal form.

The fahak is found in many streams of West Africa, but most abundantly in the Nile which it ascends from the Mediterranean It penetrates into the irrigating canals and ditches, and there lays its eggs. When the flood subsides, great numbers of the fish are left stranded and become the prey of birds of all sorts. They are also eaten by the peasants Occasionally the use of the fish as food appears to cause poisoning There is a story of two American sailors who died soon after eating the liver of the fahak Such cases, however appear to be very rare, and they are perhaps to be attributed to the use of decomposed fish On the other hand the *fugu* fishes, or Japanese species of *Tetrodon* are extremely poisonous. As in the case of the European barbel the muscular flesh is harmless but certain other parts, especially the roe, liver milt, but also the skin abdominal wall and intestines, are so poisonous that they have been used in Japan as a means of suicide and murder from time immemorial In the Asiatic seas fugu poisoning often occurs among sailors and natives and in Japan the sale of all species of *Tetrodon* is forbidden by law The fahak is a great source of delight to the Egyptian children who drive the inflated fish around and harry them until they literally burst. The children also inflate the dried fish and make handballs of them The fahak is often found in curiosity shops, where it is bought by travelers as a memento of the land of the Pyramids. The fahak was known to the ancient Egyptians. Its representation occurs twice on the walls of a temple at Deir-el-Bahari.

Photographic Dyeing.

Sunlight, which destroys many organic coloring matters, also converts some colorless and soluble inorganic compounds into insoluble colored substances, which may thus be fixed in the interior of tissues. Many experiments in dyeing fibers and fabrics by the agency of sunlight have been made, especially by Pernox and Grueve The following are some of the results obtained

Sixty parts by weight of sulphuric acid were added to a solution of 120 parts of potassium bichromate in 1,000 parts of water. White wool and silk fabrics were dipped in this solution, dried in a dark room and exposed to sunlight. A beautiful light shade of brown was produced by from 10 to 20 minutes' exposure.

Prussiate of potash gives a medium shade of blue. If white cloth impregnated with this salt is exposed to sunlight under thick paper bearing a cutout pattern, the design is reproduced in blue on the cloth, which is then rinsed in water to remove the unaltered prussiate from the parts which were covered by the paper

Others found that very [illegible] shades of blue, green, and gray can be obtained from ferrocyanides, and brownish violet, black and olive from chromates. For blue, the fabric is dipped in a solution containing 66 parts by weight of potassium ferrocyanide, 50 parts of tartaric acid and 34 parts of ammoniacal perchloride of tin, with more or less water, according to the shade desired. A short exposure to sunlight develops the blue color

For green, sulphuric acid and an ammoniacal salt are used in connection with the ferrocyanide or yellow prussiate of potash. Buff shades are obtained by producing blue, as above, and treating the dyed fabric with caustic alkali, which converts the blue compound into yellow ferric oxide.

Gray and "mode" tints are produced by treating buff (obtained as described above) with an infusion of nut galls or Campeachy wood Silk fabrics can be dyed in various shades of brown by impregnating them with copper chromate and exposing to sunlight.

The experiments prove that a certain quantity of moisture is required to produce brilliant colors with short exposure. Probably many substances which are employed in photography would produce desirable results in dyeing, but they are too expensive to be used for that purpose.

The Current Supplement.

The opening article of the current SUPPLEMENT, No 1759, is devoted to a very exhaustive discussion of the wonderful aeronautical meeting at Rheims, France. Some splendid pictures of the more prominent aeroplanes in flight are presented. One of these photographs shows no less than three flying machines in the air One of the most remarkable papers read before the Winnipeg meeting of the British Association for the Advancement of Science was that of Prof Ernest Rutherford. In this paper he explains very lucidly how the modern scientist measures the atom. The electrolytic rusting of iron is discussed by Alfred P Morgan N W Greenway writes on the comparative weights of reciprocating and turbine machinery for marine work. The most notable project for irrigation yet undertaken by the United States Reclamation Service has at last been completed, and will be thrown open to the public on September 23rd, for which reason Albert Wilhelm s excellent illustrated article on the subject of the Gunnison project (the project in question) should be read with some interest. Prof Albert F Ganz of the Stevens Institute of Technology writes thoughtfully on the progress in electric current development in the artificial lighting field A good practical article which will be read with profit by the amateur is Clarence Biggs's "Fitting Electric Bells." Dr D T Macdougal of the Carnegie Institution, one of our greatest biologists, writes on aridity and evolution Prof T J J See has the distinction of being what may be called an astronomical revolutionist. In a paper entitled "The Origin of the Satellites" he sets forth his theory that satellites are in reality captured bodies, and that they did not spring from parent planets as we now suppose.

Official Meteorological Summary, New York, N. Y., August, 1909.

Atmospheric pressure Highest, 30.26, lowest, 29.50, mean, 30 01 Temperature Highest, 93, date, 9th; lowest, 58, date, 4th; mean of warmest day, 82, date, 9th, coldest day, 62, date, 17th, mean of maximum for the month, 78.7; mean of minimum, 64.5, absolute mean, 71 6, normal, 72.6, deficiency compared with mean of 39 years, 1.0. Warmest mean temperature of August, 77 in 1900, coldest mean, 69 in 1903. Absolute maximum and minimum of August for 39 years, 96 and 51 Average daily excess since January 1st, 1 2. Precipitation 7 94, greatest in 24 hours, 5.06; date 16th-17th, average for August for 39 years, 4 64. Accumulated excess since January 1st, 1.15. Greatest precipitation, 10 42, in 1875, least 1 18, in 1884. Wind: Prevailing direction, northwest, total movement, 7,610 miles, average hourly velocity, 10.2; maximum velocity, 40 miles per hour Weather Clear days, 12; partly cloudy, 10, cloudy, 9; on which 0.01 inch or more of precipitation occurred, 9. Thunderstorms: 19th, 20th. Mean temperature of the summer, 71.73; normal, 71.80 Deficiency, 0.07 Precipitation, 13.09; normal, 12.17 Excess, 0.92.

The "Panflex" spring wheel, invented by Hon. R. C. Parsons, of turbine fame, shown in operation at the recent conversazione of the Royal Society, is an invention which has for its object the easy motion of a vehicle when run at low or high speeds. This ease of motion is due to the springs being capable of deflection in every direction. The wheel is consequently [illegible], according to its distinguished inventor, and not subject to bursts or punctures, [illegible] case of wheels fitted with pneumatic [illegible] and tear are small, and should a [illegible] is [illegible] the case [illegible] in a few minutes [illegible]

A SLIGHT ERROR CORRECTED

To the Editor of the SCIENTIFIC AMERICAN

On page 125 of the SCIENTIFIC AMERICAN of August 21st is an article headed A Record Cross-Country Motor-Boat Trip," in which you place the location of dam No. 6 at Rochester, Pa. Dam No 6 is located about five or six miles below Rochester while dam No 5 is located at Freedom about one and one-half miles above Rochester and twenty four miles below Pittsburg This is a small error and perhaps need not be corrected My only excuse is that I am an interested reader of your paper and have a few moments time to spare DEWITT HOWE

A HEAT PARADOX

To the Editor of the SCIENTIFIC AMERICAN

The fact can be discovered by the physical experiment, that if a conducting rod is heated and then partly cooled very rapidly the quick cooling will increase the temperature of the still hot adjacent section

Therefore a paradoxical phenomenon of heat being directly generated by cold can be demonstrated which depends on the conductivity of the rod and the proportion of the part cooled

The degree of this increase of temperature is directly proportional to the heat of the rod and the degree and the quickness of the cooling.

Force used by the heating in expansion is retransformed into heat of rapid contraction by quick cooling and is conducted along the rod faster than the cold it being yet partly hot and increases it in temperature that can be measured which proves that force from the rapid contraction caused by the quick cooling is conducted along the rod as heat

EARLY SUGGESTIONS OF INVADING ENGLAND BY BALLOON

To the Editor of the SCIENTIFIC AMERICAN

The recent crossing of the English Channel by M Blériot has aroused worldwide attention It may be interesting to know that in June 1803 Boulard and Le Campion two French cartoonists predicted the invasion of England by a balloon Boulard s drawing is entitled La Thilorière or the Descent on England Design for a Montgolfière (balloon) capable of carrying 3 000 men and which will cost only 300 000 francs There will be fixed to it a lamp which will give out a volume of flame sufficient to prevent its cooling Extracted from the Publiciste of Thursday 13 Prairial of the year XI [2 June 1803] Paris chez Boulard No 175 Rue St Denis etc Campion s picture designed and engraved by Echard is called The Tower of Calais, new aerostatic machine constructed by M Romain by order of the government to cross from France to England in conjunction with M Pilatre de Rozier A third and still more curious plate shows the invasion of England as carried out by the combined operations of warships flat-bottomed boats, and balloons of all shapes and sizes, while cavalry and artillery approach Dover through a subterranean passage A glance at these cartoons which are reproduced in Messrs. Wheeler and Broadley s interesting work entitled "Napoleon and the Invasion of England shows that the Frenchmen of that period had some gift of prophecy fanciful though it was Although no airships have been built to carry 3 000 men still Zeppelin's exploits come close to realizing the dream of the French artist GERALD ELLIS CRONIN

SHEET LIGHTNING

To the Editor of the SCIENTIFIC AMERICAN

In connection with Mr A. A. Graham s letter in the issue of August 28th 1909 I would like to say that the facts at our disposal at the present time would seem to indicate that sheet lightning is to be expected at high altitudes.

First The atmosphere is very rare.

Second It is probable that the atmospheric dust if not wholly lacking is present in but small quantities, of the lightest material.

Third The temperature is low and the clouds are very apt to consist of minute ice crystals.

If it is correct to reason from the laws governing the discharges of an induction coil, we may draw the following conclusions:

Likening the sheet lightning to the so-called spark of the coil, we can safely say that such a discharge is unable, owing to the lack of dust, to form an incandescent path.

If the sheet lightning is compared with the brush discharge of the coil, the following facts are brought out:

The thinness of the air would tend to produce sheet lightning.

The action of the crystals, [illegible] [illegible] the same way as a [illegible] piece of varnished cambric placed between the terminals of a coil.

Such discharges would be noiseless.

In conclusion I would like to ask if any of your readers have satisfactory explanations of the coloring (violet to yellow) of lightning flashes

LATIN-AMERICAN TRADE

To the Editor of the SCIENTIFIC AMERICAN

Do you know that the total foreign trade exports and imports of the twenty-one republics including the United States in 1907 was $5 500 000 000?

Do you know that of this the share of the twenty Latin American republics was $2 077 000 000?

Do you know that these figures show that Latin America does more than one-third of the total commerce of the American republics divided as follows

Exports to foreign lands	$1 072 000 000
Imports from foreign lands	1 005 000 000

Do you know that further analysis of these figures shows a total foreign trade between Latin America and the United States of $558 000 000?

Do you know that this total represents only about one-fourth of the total foreign trade of the sister republics of the United States divided as follows

Exports to the United States	$318 000 000
Imports from the United States	240 000 000

Do you know that these figures show a balance of trade against the United States of approximately $78 000 000 a year?

Do you know that the Latin American countries bought last year from other nations than the United States $756 000 000?

Do you know that from the United States these countries purchased only $240 000 000?

Do you know that Latin America purchased more than three times as much from other countries as she did from the United States?

This demonstrates the great possibilities of trade development for the United States in Latin America

John Barrett in a speech before the Trans-Mississippi Commercial Congress in San Francisco October 6th 1908 said

Without unwarranted enthusiasm let me point out to you my confident belief that the next ten years will be a Latin American decade—that all the world will be then studying and watching Latin America as it now does Japan and the Orient and that a material economic intellectual and political advancement will be witnessed in Latin America which will rival what has been accomplished in the United States Were it not for the lamentable ignorance which prevails throughout the United States in regard to the peoples institutions resources and governments of this section of America this statement would not seem in the least surprising Those of us who have traveled from Cuba to Chili and from Brazil to Bolivia are keenly aware that this great onward movement has already begun and that Latin America has entered upon a new era of splendid activity and world wide influence

Twenty republics varying in size from the area of Brazil which is larger than that of the United States proper by 200 000 square miles to Salvador the smallest which would take in Rhode Island six times over having a combined population of nearly seventy millions and a foreign commerce valued at more than $2 000 000 000 per annum are going ahead so rapidly that no man can safely prophesy the limit of what they will accomplish during the next ten years Gifted with a variety of climates and of resources blessed with a marvelous intermingling of cool plateaus and tropical lowlands, provided with vast navigable river systems and long extent of accessible coast line supplying numerous important products which the rest of the world must purchase and possessing great mineral wealth and a people of deep sympathies and high intellectuality based on an old and worthy civilization they all challenge our best study and keenest appreciation

I am indebted to the International Bureau of American Republics for the above data

New York, N Y ALFRED J THOMPSON

TREES AS WITNESSES IN EARLY SURVEYING

To the Editor of the SCIENTIFIC AMERICAN

Your very interesting account of Making a Tree to Speak in the issue of the SCIENTIFIC AMERICAN of August 14th is rendered more complex in Pennsylvania than in the West for two reasons First by the system of surveys or rather the lack of system in the early surveys, and second by the fact that they are much older and consequently much harder for a surveyor to determine Throughout northern and eastern Pennsylvania the surveys were made at dates varying from 1749 to 1804 The earliest surveys were isolated tracts, usually taken up by settlers and surveyed by authority of warrants granted by the Proprietors to the applicants and executed by a deputy surveyor to whom the warrant was directed About 1767 explorations were made by agents of the Proprietors of the river valleys and in 1769 large areas were sold to settlers and the lines run and marked upon the ground by what Mr Cooke calls the blazed line or by chopping off a small slice of bark from the opposite sides of the trees which the surveyor passed The corners of the surveys were usually marked by cutting three notches in the corner tree in the direction from which the surveyor approached it and on the side from which he left it Besides this corner tree the surveyor marked other trees standing near by with three notches on the side facing the corner tree and called witnesses These surveys of 1769 were located in the river valleys and generally at the mouth of some stream of considerable size affording abundant water power as it came to the river In 1772 the surveys were extended up the smaller streams sometimes for long distances taking the land which was deemed tillable and this plan was followed until 1789 At this date there arose a great demand for the lands and large bodies were sold by warrants to the applicants who had them surveyed and frequently the surveyor had no regard for the previous surveys and laid the new warrants on top of the older ones In the year 1793 a company known as the *Holland Land Company took warrants for* thousands of acres located in the northern part of the State and sent surveyors to make the location Again these surveyors paid no attention to any of the former surveys and used the same style of marking as had previously been used by the older surveyors In 1802 to 1804 the surveyors from the State of Connecticut claiming under the original charter granted by the King of England extending from the Atlantic to the Pacific came into the State and began their surveys and again used the same system of marking paying no attention to any of the former surveys This act led to what is termed in history the Pennimite and Yankee war which later by the decree of Trenton decided that the Connecticut settlers should hold seventeen townships in Luzerne County but that the State of Connecticut should release all its claim to other parts of the State of Pennsylvania

Now after the lapse of from one hundred and seven to one hundred and sixty years the surveyor finds difficulty with the full meaning of the word in determining how these old surveys were located The timber in many places was removed before the lines were fully settled and where it remains it requires a great amount of skill on the part of the surveyor to detect the traces of the ax marks in the bark of the trees and still more skill to count the rings to determine to which set of surveys the mark belongs This difficulty is increased by the fact that the old surveyors were careless in their locations and occasionally the marks are found as much as two miles from where they purport to be and the courts hold that the monuments on the ground are the controlling factor in making the location

To show the importance of making a tree speak to determine a location a surveyor recently had occasion to retrace the lines of a survey made sixty years ago The corners were all obliterated Some had been trees some were called stones and one was called a pine knot A dispute arose over the location of the pine knot A surveyor was called and after trying in vain to locate the pine knot from the other corners as called for came upon a marked line tree bearing the date of this particular survey and traced it out until he came to a point where tradition said the other line of the survey came to the pine knot Making search he found a marked tree on that line and bringing the two lines to an intersection on the bearings called for was preparing to set a permanent monument when a workman dug up a piece of wood On examination this proved to be the pine knot in question By removing the accumulation of decayed wood and dirt the notches with which it had been marked were so clearly discernible that the location was settled

Different kinds of timber show a variety of ways of healing over the cut and some become so overgrown in a few years that they are more difficult to determine than some other species after a much longer period The various species of pine lose the marks in a few years where they are of rapid growth because the bark shells off Some species of oak and the hemlock will hold a mark for a long time and frequently it is found that the marks show very plainly after a lapse of over one hundred years In the Connecticut survey above referred to some corners were trees on which Roman numerals were cut and yet after a lapse of over one hundred years the letters can be found in the old wood of the tree by cutting away the new growth which has closed over the flattened surface where the numerals were cut So taking it all, the trees do speak and tell an indisputable story and stand as silent witnesses to the hardships of the surveyors of that early day in climbing over the mountains and leaving their trail in the timber to be found by future generations

Millville Pa BOYD TRESCOTT

COMMANDER PEARY'S DISCOVERY OF THE NORTH POLE

The amazing coincidence of the report by two independent explorers of their location of the North Pole within a year of each other after the hardship privation and expense of life and funds endured in vain in the effort to find it for over three hundred years makes any comparison of the probability of the reports or the value of the results obtained difficult if not unprofitable with the limited particulars hitherto available

We prefer therefore to await the verdict of the investigation which will undoubtedly be made by the highest scientific authorities upon presentation of the complete evidence on either side and expressing no opinion briefly to summarize Mr Peary's report of his achievement as we did that of Mr Cook

The origin and early history of polar exploration was sufficiently outlined in last week's SCIENTIFIC AMERICAN which also compared the reported achievement of Cook with the earlier work of Peary After the latter expedition of 1906 when he reached 87 deg 6 min N lat then the farthest north he determined to make one more effort to reach the Pole and the Roosevelt was accordingly equipped by the Peary Arctic Club with all the material and scientific instruments which have been proved to be most essential in polar exploration by Commander Peary's twenty three years of experience

The Roosevelt with Peary and his party on board left New York on July 6th 1908 called at Sydney near Cape Breton Nova Scotia leaving there July 17th and proceeded east round Newfoundland and then straight north through Davis Strait and Baffin's Bay to Cape York Greenland at the southern end of Smith Sound Leaving there August 1st the ship proceeded *via* Etah farther up the sound navigating laboriously through floating ice often densely packed to Cape Sheridan Grant Land the northern end of Ellesmere Land and on the other side of the sound arriving there September 1st and here the expedition passed the winter The farther progress of the explorers has been reported by Commander Peary exclusively to the New York Times, by whose courtesy we are permitted to give the following abstract.

Peary's full report describes greater difficulty in making the point selected for winter quarters than was at first anticipated. An actual landing at Cape Sheridan was not made until several days after arrival there, strong northeasterly winds and the drift of the ice repeatedly forcing the ship back and twice driving her aground, and it was only on September 5th, after zigzagging through leads in the ice for several days, that the "Roosevelt" succeeded in rounding Cape Sheridan into open water and lying up in an opening in the floe at the mouth of the Sheridan River

Supplies and equipment were immediately transferred across the ice to a clapboard house and storeroom hastily built on shore, and on September 15th the work of transporting supplies was begun, several sledge expeditions depositing provisions at various points along the coast from Cape Sheridan to Cape Columbia, so that the sledge party on its spring dash for the Pole might travel as light as possible and pick them up en route This work was carried on continuously until November 5th and was mingled and followed by hunting expeditions tidal and other observations by various parties lasting until February

The sledge expedition for the Pole left the Roosevelt in three divisions on February 15th 21st and 22nd under Capt Bartlett, Prof Marvin and Com Peary respectively the total of all divisions being 7 whites and 59 Esquimaux, with 23 sledges drawn by 140 dogs.

All of the divisions appear to have assembled at Cape Columbia, such of the supplies as were required being brought up from the other depots on the route the dogs rested and the equipment thoroughly overhauled by February 27th In the meantime, apparently Bartlett's pioneer division had been hewing a way north through jagged ice to the big lead, a stream of open water which he crossed on the first of March and got away north over the ice the remainder of the party following soon after but being stopped on their second day's march by open water formed by a breach of the ice by strong wind after Bartlett's division had passed the spot Two sledges were smashed beyond repair in the first march, the teams going back to Cape Columbia for reserve sledges. At the end of the fourth

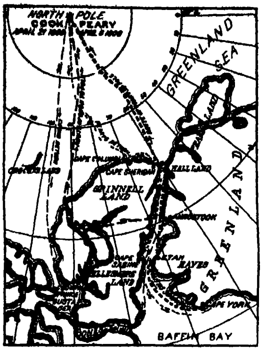
SCENES ON THE COOK AND PEARY EXPEDITIONS.

day the rest of the expedition caught up Bartlett, who had been stopped by open water, which delayed the entire party till March 11th.

On the 5th of March the sun appeared for a few minutes at noon for the first time after the long winter night On March 11th the lead was sufficiently frozen over to be crossed, and another start was made. Borup and Marvin, who had gone back for alcohol and oil from Bartlett's third camp had not yet come up with the expedition in spite of the delay causing some anxiety but a note was left for them and three days later they caught up the main party at the end of its sixth march The latter in the meantime had been traversing alternately floating solid ice and newly frozen leads, and had just crossed the 84th parallel From that camp Dr Goodsell turned back by prearrangement and McMillan accompanied him reluctantly owing to a badly frozen foot, which he had been concealing for three days much to the regret of Peary who had counted on his enthusiasm and physical powers

The best dogs and sledges were selected for the northward journey the party now consisting of 16 men 12 sledges, and 100 dogs At the end of the tenth march at latitude 85 deg 23 min Borup turned back in charge of the second supporting party The traveling rather improved and Commander Peary and Marvin waited twenty hours after the start of the advance party in order to overtake them as they broke camp after the next halt, thus using the same camp and keeping in touch with the advance party once in every twenty four hours. After two more marches the sun began to get high enough for observations to be made 85 deg. 48 min being recorded and the going continuing to improve 50 minutes was covered in the next three marches including 20 miles on the third day bringing the party to 86 deg 38 min At this point Marvin turned back with the third supporting party The next day s march was good but after that came the deepest snow encountered accompanied by haze which made a short and exhausting journey At the end of the succeeding day the ice parted exactly where the party was encamped nearly causing the loss of dogs and sledges but after an exciting period dashing from one moving floe to another better going was reached Then came Capt Bartlett s last day another long march with fair going camp being made at 87 deg 48 min as shown by observation of the sun next day The sturdy navigator of the Roosevelt who had borne the brunt of the pioneering work walked several miles north in the morning to be sure that he crossed the 88th parallel and then turned reluctantly back with the two Esquimaux of the last supporting party the provisions carried being insufficient to last more than 6 men and 40 dogs for the week or more estimated to be required to reach the Pole as well as for the return journey

Peary then determined to try and reach the Pole in five forced marches allowing less than a day for each, extending the last one if necessary to complete the distance lacking. His cabled narrative speaks of five marches of fifteen miles each but as he was then south of the 88th parallel this is an obvious mistake for 25 miles to which distance he refers as having accomplished his intention on his next the twenty first, march. After a few hours sleep good going was found and twenty miles were covered on the twenty-second march before an open lead delayed the journey Another brief halt and even better weather and smoother ice enabled another twenty miles to be made on the next march including a dash across 100 yards of ice newly formed over a lead which buckled under the sledges and broke as the last one left it Again a short sleep and twenty five miles were made on the twenty fourth march Although the temperature was not so low as had been experienced even the Esquimaux complained of the bitter cold Much needed sleep was taken for a little longer and then the party dashed forward dreading that each rise in the ice marked an open lead but always finding continued going The haze was thicker but an observation was possible at noon showing 89 deg 25 m A rise in temperature to 15 deg below zero encouraged the dogs, and forty miles was covered in twelve hours An observation at noon on April 6th at the end of the twenty sixth march showed latitude 89 deg 57 m to have been reached only three minutes or a little over three miles from the Pole so the remaining distance was apparently covered before a rest was taken



Map showing the routes taken by Peary and Cook on their expeditions

The first thirty hours at the Pole was spent in making observations and taking photographs Ten hours after arrival the weather cleared and the afternoon of April 7th was cloudless A crack in the ice five miles from the Pole was found and a sounding was made 1 500 fathoms of wire finding no bottom and the wire being broken and lost in withdrawing it.

Speed was just as urgent on the return as on the upward journey every day gained lessening the chance of a gale opening leads and destroying the track Every march back lessened the chance of provisions running short before the base was reached so the equipment could be lightened to facilitate speed Peary therefore determined in spite of the records for Arctic travel made on the advance to try to [illegible] the daily journey on the return covering two of the northward marches on each march south and making use of the same igloos —the ice huts made in camping—and so saving time at each halt This he very nearly accomplished regularly covering five outward marches in each three of the return journey He was singularly fortunate in escaping open leads in the ice which had delayed the return of the supporting parties down to lat 85 deg 23 m the camp at the end of the tenth outward march where a lead five miles wide was encountered By good luck Bartlett s trail was found again at the other side and by continued rapid traveling Cape Columbia was reached on the 23rd of April after fifteen marches The Roosevelt was reached in two more marches and found unharmed Nearly two months were spent in additional geodetic observations and in bringing back remaining supplies from the outlying caches until on July 18th the ice was sufficiently open for the ship to be removed from her berth She fought her way south to Cape Sabine by August 8th picked up Whitney and the stores at Etah coaled from the Jeanie and cleared from Cape York August 26th and reached Indian Harbor September 5th to send the now historic telegram Stars and Stripes nailed to North Pole

How the sextant is manipulated in measuring the sun's altitude.

HOW COOK MADE HIS LATITUDE OBSERVATIONS

So much doubt seems to have been engendered in the public mind by a certain portion of the press regarding the validity of Dr Cook s observations that it may not be amiss to describe briefly the methods which in common with every other explorer he would necessarily adopt in determining his latitude The actual determination of latitude although it is one of the most important practical questions in astronomy is also one of the most elementary for which reason we fail to understand why so much ado should have been made

For the purposes of astronomical measurement the celestial sphere is divided as indicated in Fig 1 Assuming that the observer is placed at *O* his celestial horizon will be *H F S W* The axis of the heavens will be *P p P* being the elevated pole and *p* the depressed pole *Y* will be the zenith of the observer and V his

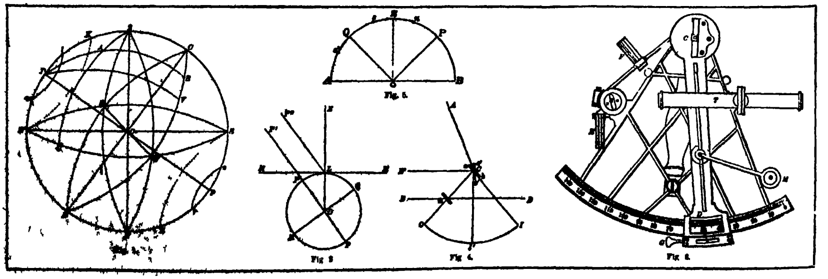

Fig. 5.

Fig 3

Fig 4.

Fig 2.

Diagrams showing the principle of the sextant and the manner of its use in determining the altitudes of celestial bodies.

nadir The great circle $HZSN$ will be the observer's celestial meridian like all great circles passing through the celestial poles It is an hour circle or circle of declination The circle $EQWD$ is the equinoctial (the celestial equator) and the circle $EZWN$ perpendicular to the meridian is the prime vertical cutting the horizon at E and W, respectively the east and west points The north pole of the heavens is P and is marked by the Pole Star or North Star

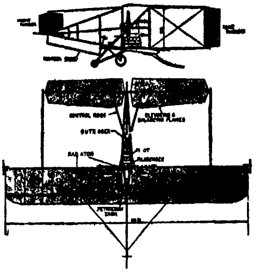
The latitude of any place on the earth is equal to the altitude of the elevated pole at that place Hence by measuring the altitude of the Pole Star the north latitude of a place above the equator is directly obtained This follows from a consideration of Fig 2 in which Pp is the earth's axis and EQ the equator The line HR tangent to the earth's surface at L is the horizon and the point Z the zenith of L Assume that the earth's axis and the line LP parallel to the earth's axis to be both indefinitely prolonged Because of the immensity of the celestial sphere as compared with the earth these two lines will sensibly meet at a common point on the surface of the celestial sphere and this common point is the elevated pole To an observer L this elevated pole will therefore lie in the direction LP' and $P'LH$ will be its altitude From Euclidian geometry we know that the angle HLZ is equal to the angle POQ and the angle ZLP' equal to ZOP Hence the angle $P'LH$ (the altitude of the pole) is equal to LOQ the observer's latitude

The latitude of a place on the earth is also equal to the declination of the zenith at that place The declination of a body or point is its angular distance from the plane of the celestial equator and hence ZOQ in Fig 2 is the declination of the zenith or latitude of L in Fig 2

In order to calculate his latitude the navigator or explorer employs a sextant which is an instrument by means of which the angular distance between two visible objects can be measured Since Pole Star observations cannot always be taken because the horizon is not always visible at dusk or at night time the navigator is generally compelled to measure the sun's altitude and to use that as the basis of latitude calculations As shown in Fig 3 the sextant is a sector of a circle whose arc measures 60 deg A movable radius called the index bar CD revolves about the center of the sector At its lower extremity the bar carries a vernier D At the upper extremity of the index bar is a silvered mirror C the surface of which is perpendicular to the plane of the instrument Another glass K called the horizon glass is rigidly attached to the frame of the instrument the upper half of which glass is transparent and the lower half silvered The surface of the horizon glass must also be perpendicular to the plane of the instrument A telescope T is directed toward the horizon glass with its optical axis parallel to the plane of the instrument. Two sets of colored glasses F and F are usually provided for the protection of the eye when the sun is observed The sextant is constructed on the principle that the angle between the first and last direction of a ray which has been reflected twice in the same plane is equal to twice the angle which the two reflecting surfaces make with each other

Suppose that we wish to measure the angular distance between the sun A and some distant object B on the horizon (Fig 4) The object B is distinctly visible at D in the telescope through the upper transparent half of the horizon glass m. The object B is so distant that the rays BC and BM coming from it may be regarded as sensibly parallel If CI and CI are the positions of the index glass and index bar when both glasses are parallel the ray BC will be reflected by the two glasses in a direction parallel to itself and the observer whose eye is at D will see both the direct and the reflected image of B in coincidence If the index bar be moved to some new position CI so that the ray from the sun A is finally reflected in the direction mD then the observer will see the direct image of B and the reflected image of A in coincidence The angular distance between the two bodies is evidently equal to the angle between the first and the last direction of the ray AC which angle is equal to twice the angle made by the two glasses with each other or twice the angle ICI If then we know the point I on the gradient arc at which the index bar stands when the glasses are parallel twice the difference between the reading of that point and that of the point I will be the angular distance of the two bodies To avoid this doubling of the angle every half degree on the arc is marked as a whole degree

The sun is the body generally used by navigators in determining latitude The time of noon being approximately known the observer begins to measure the altitude of the lower limb of the sun a few minutes before noon and continues to measure it until the sun ceases to rise, or dips as it is called. The greatest altitude attained by the sun is taken as the meridian altitude Corrections are made for index error dip, atmospheric refraction, parallax, and semidiameter and the result is the sun's true meridian altitude. Taking this from 90 deg. we obtain the sun's zenith distance Looking in the Ephemeris or Nautical Almanac we find the sun's declination given for Greenwich (or Washington) noon of every day, with the hourly change so that we can easily deduce the exact declination at the moment of observation. Then the observer's latitude is obtained because the latitude of the observer equals the sun's zenith distance plus the sun's declination This is apparent from a consideration of Fig 5 in which the circle $AQPB$ is the meridian Q and P the equator and the pole and Z the zenith QZ is the declination of the zenith or the latitude of the observer If the sun is observed at s south of the zenith as it crosses the meridian then Zs is its zenith distance and Qs its declination which is known Then QZ equals $Qs + sZ$ in other words the latitude equals the declination of the sun plus its zenith distance



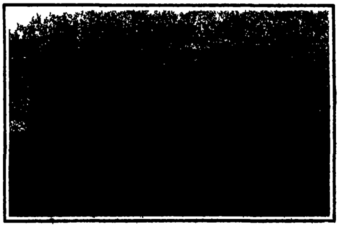
Plan and side elevation of Capt Cody's biplane.

The handling of the sextant is so simple a matter and the application of corrections to its readings so easy that we fail to understand how anyone can seriously doubt Dr Cook's accuracy

◆

CAPT CODY'S BRITISH ARMY AEROPLANE.

Following close upon the great exhibition of flying which was given recently at Rheims Capt S F Cody who has been working for a number of years in the interests of the British government has met with complete success with his aeroplane and has succeeded in accomplishing a cross-country flight of one hour and three minutes duration, in the course of which he rose to a height of about 400 feet circled a church steeple and traveled altogether about 47 miles. This is the first flight demonstration of any account which has been given in England and the fact that it has been accomplished by an American after persistent experimenting puts another aviation record to the credit of the United States.



Capt Cody in flight in his latest biplane.

CAPT CODY'S BRITISH ARMY AEROPLANE.

Capt Cody has made a few minor changes in his machine since it was illustrated by us in our issue of January 30th last. Chief among these is the dividing of the single-surface horizontal rudder in front of the machine into two separate planes, or wings, placed side by side and arranged so they can be worked together or separately and in opposite directions. This division of the horizontal rudder into two parts has been substituted for the [illegible] wings, or balancing planes, which were formerly placed at each end of the single surface By inclining the two wings of the present rudder in opposite directions, the machine can be righted when it tips to one side or the other, and this movement of the wings can also be used in steering the aeroplane to the right or the left. Steering in a horizontal plane is accomplished chiefly by means of two vertical rudders—one in front above the horizontal rudder and one some distance at the rear of the planes

The Cody biplane is mounted upon three wheels and one skid Two of the wheels, which are about 2 feet in diameter are placed side by side just under the front edge of the lower plane while the third one is located in advance of the other two and at the intersection of two pairs of heavy inclined uprights extending downward from the rear longitudinal of the upper plane and from beneath the bed of the motor respectively The former pair of inclined uprights carries seats for the aviator and his passenger the latter seat being a foot or more above the aviator's seat and just in front of a radiator consisting of long thin tubes extending upward to the front edge of the top plane A single skid extends backward from the rear edge of the lower plane on the center fore-and-aft line of the machine Most of the weight of the aeroplane is carried upon the two large wheels placed beneath its front edge Coiled-spring shock absorbers surround the upright rods extending from the axle of these wheels to the lower edge of the front plane. If the machine tips downward in front when running along the ground, the weight is taken by the small wheel in front, while if it tips upward the skid at the rear touches the ground This skid also acts as a brake when alighting The use of the inclined uprights extending out in front, and also the use of bamboo to support the rudders makes Capt Cody's biplane somewhat similar in construction to that of his fellow countryman Mr Curtiss.

The main planes of Capt Cody's machine are 52 feet long by 7½ feet in a fore-and-aft direction They are spaced 9 feet apart at the center this distance gradually diminishing to 8 feet at the ends. Both planes are arched slightly in a transverse direction, the upper one being curved downward somewhat more than the lower one in order to bring it nearer to the latter at the ends The ends of both planes moreover are almost flat although the other parts of the surfaces have the usual parabolic curve In arching these surfaces downward Capt Cody has followed the idea of the Wright brothers who claim that a slight downward curvature of the ends of the planes is preferable to an upward curvature of them In the June Bug" biplane of the Aerial Experiment Association it will be remembered that the upper plane had its ends curved downward, while the ends of the lower plane were curved upward This arching of the surfaces in opposite directions was we believe the idea of Lieut Selfridge and it was found to work very well.

The wings of the horizontal rudder are also arched slightly in a similar manner to the main planes These are operated by a horizontal steering wheel mounted upon the end of a universally pivoted lever Swaying the wheel from left to right or *vice versa* sets the wings of the horizontal rudder so as to right the machine when it tips while turning the wheel moves the vertical rudders in front and behind and also inclines the wings of the horizontal rudder slightly in opposite directions in order to tip the machine downward as it makes a turn; pushing forward the steering wheel or pulling it backward causes the two wings of the horizontal rudder to move together and inclines them downward or upward, in order to direct the machine in either of these two directions Capt Cody has also provided for auxiliary balancing planes at the ends of the main planes. These can be attached to the uprights half way between the planes, if they are found necessary, in order to tip the machine in making abrupt turns. The inventor has also provided for warping the main surfaces if he finds this necessary He has employed a system of warping the wing extensions of box kites for some time past with the man lifting kites with which he has experimented If it was found that the kite was not riding properly by hauling it down and warping the wing extensions of the main box the trouble could be remedied

The power plant of the Cody machine now consists of an 8-cylinder E N V. gasoline motor capable of developing about [illegible] horse-power This motor has replaced the [illegible]-horse-power Antoinette which he used early in the year It has been moved slightly back from the front edge of the lower plane, instead of being placed forward of the front edge as heretofore. In other words, the positions of the motor and [illegible] have been [illegible] [illegible]. [illegible]

(Continued [illegible])

Handy Man's Workshop

A HANDY TAP WRENCH.

BY EDWARD [illegible]

A wrench for holding machine taps or reamers and the like can be easily made of a piece of flat steel and two machine screws. If steel is not handy iron can be used Take a piece of stock of about ⅜ x ¼ inch, and cut off two lengths of 5 inches each. Near the end of these pieces and about 1 inch apart drill two holes, ¼-inch tap holes in one and clearance holes in the other Centrally between the holes file V shaped grooves about 1/16 inch deep Tap out the holes and assemble the parts using round head screws of ¾ inch length The ends of the wrench should be rounded for convenient handling The dimensions herein given can of course be varied at will Any size from the smallest to the largest can be made in this way

A HANDY TAP WRENCH.

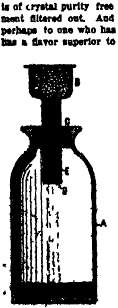
THE COLD PROCESS OF MAKING SIRUP

BY THALSON [illegible], C E

The customary way of preparing table sirup is to pour boiling water on sugar or set a pan of water on the stove to boil, with sufficient sugar to sweeten and give body to the water Sirup for canning is almost invariably made by one of these methods although neither one enables the housewife to obtain a finely-flavored clear fluid

Sugar when put in boiling water or in cold water that is raised to the boiling point seems to lose its delicate flavor the resulting sirup is frequently stained, rather faintly yellowish or bluish according to the composition of the vessel in which it is prepared This stain may be due to the chemical salts in the water, which are made active to color sugar by being subjected to heat or the stain comes from the tinned or glazed material of the vessel given off when hot in the presence of water and sugar It may of course originate from the chemical reactions set up in the water only when the water is in vessels of certain composition and the stain may be unnoticeable when vessels of other composition are used But where a stain in the sirup cannot be detected there will always be found a gritty sediment in the sirup pitcher after cooling This is due to the impurities of commercial sugar

There is another and better method of making sirup than by the aid of heat It is the cold process By this simple method the sirup resulting has a body that is of crystal purity free from stain and with the sediment filtered out. And what is of more importance, perhaps to one who has a discerning palate the sirup has a flavor superior to that produced by cooking or by the application of heat however moderately



THE COLD PROCESS OF MAKING SIRUP.

My father was a druggist and chemist of near thirty years' practice He began to make all his sirups very early in his career and obtained quite a reputation among physicians in his locality for the quality of them I have depicted his method which makes the sirup and filters it all in one operation using instead of the chemist's apparatus, such articles as almost any housewife can find in her kitchen, and can assemble easily

The parts required in this home-made apparatus are a bottle A of about a quart or more capacity an Argand lamp chimney B two corks, C and D, and a bit of cotton E, for a filter A large-mouthed bottle, having a well-fitting cork, is preferable to a glass [illegible] or Mason jar, as the cork C is already fitted to it. With cork C placed on a board or table, the circumference of the Argand chimney is marked on its upper surface, and a hole is cut through the cork, a little less than the mark indicates. Care must be taken to cut this hole so that the chimney will fit in [illegible] for cutting which, a sharp-pointed knife will do, [illegible] cutting edge, is a better tool to use The smaller cork D is fitted within the Argand chimney and one or more small holes are bored through it the holes may be burned by means of a red-hot wire

If a funnel be substituted for the Argand chimney, the large cork C may be dispensed with and if a bottle is used having a neck that will admit the Argand chimney's long cylindrical tube but not its funnel-shaped base no cork need be used with the chimney either but the use of a cork is preferred as it prevents the dust from getting in and keeps the water in the sirup from evaporating In use the parts are assembled as shown in the drawing and pure granulated sugar is poured into the chimney until the tube part is filled Over this filtered water is poured and the top is then covered to exclude dust

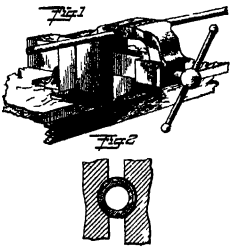
Immediately the manufacture of sirup begins. The process must not be hurried The rate at which the sirup drops into the bottle must be regulated by the size of the hole through the cork D also the thickness of the cotton E and the density it is packed home against the cork If the sirup is made too rapidly it drops down diluted By regulating the filter the control of manufacture is assured Filter paper of suitable texture for filtering sirups may be substituted for the cotton a rapid filter paper and cotton would make an ideal strainer to clarify the liquid as it forms and seeks to escape

The sirup made by filtration—as a chemist would call the process—has a taste of rock candy By suspending threads in the sirup crystals of sugar will grow upon them popularly known as rock candy These crystals by the way are better than ordinary sugar to sweeten a teacup in the opinion of some connoisseurs As a medium in which to preserve cherries peaches plums in fact any whole fruit to use when serving liquors it is immeasurably superior to boiled sirup Cherries hard cooked and suspended in it may be incased in solid crystals of rock candy With thought and ingenuity many novelties may be devised with it as one of the ingredients

VISE FOR POLISHED PIPE

BY A V SHARIN JR

A very good way to hold pipe or rods that have a polished surface is to sprinkle dry plaster of Paris on heavy paper and roll the article to be held in the paper taking care that there is plenty of the plaster between the paper and the pipe or rod Place the roll between blocks of wood having a hollow face and clamp firmly in an ordinary bench vise If upon removing the paper the plaster is found to adhere to the pipe in hard cakes do not try to scrape it off but wash the pipe in clean water which will loosen the plaster and leave the surface in a perfect condition Another method is to place the pipe between pieces of lead sprinkled with plaster and use a pipe vise for a clamp.



VISE FOR POLISHED PIPE

TEMPORARY REPAIRS TO BROKEN SPRINGS.

A spring is most apt to break in the center as in Fig. 1 The spring clips A A will probably hold it together after a fashion but the ends will sag and put a dangerous strain on the clips A hard wood board B, from 1 inch to 2 inches thick should be procured and the sides trimmed down so that it will be about 5 inches wide in the center and 2 or 3 inches wide at the ends. Drive nails CC in the ends of the board jack up the frame of the car to take the weight off the spring put the center of the board on the rubber bumper D or if there is no bumper on a suitable block of wood and bind the ends down tightly to the spring with leather straps or clothesline

Fig 1.—REPAIRING A SPRING BROKEN AT THE CENTER

In case the breakage is toward one end a block E Fig 2 should be nailed to the board over the break The remainder of the operation is substantially as shown in Fig 1 When clothesline is used the winding should start at the end of the board the short end of the rope being tied in a single knot and led along the board and covered by the subsequent turns

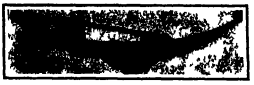


Fig 2—REPAIRING A BREAK AT ONE END OF THE SPRING

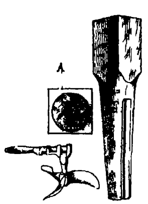
SIMPLE TAPERED REAMER

BY ALBERT F BISHOP

A simple tapered reamer for fitting a propeller wheel to a shaft that might have an odd taper may be made out of a tough piece of hickory turned in a lathe to the same taper and size of the shaft Leave a square end on the hickory piece as shown in the illustration Cut a quarter inch groove full length in the tapered part snugly inserting a quarter-inch square piece of steel in the groove Self hardening steel is perhaps obtainable Be sure to bevel the cutting edge which is marked A in the illustration to prevent the cutter from digging in The steel is backed up with three set screws which may be turned with a screw driver to slightly adjust the taper and make a perfect fit Use a fair sized monkey wrench in rotating the reamer The writer fitted a propeller wheel in a few minutes with this device

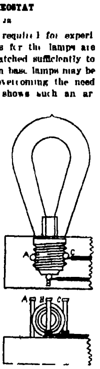


A SIMPLE TAPERED REAMER

A CHEAP LAMP RHEOSTAT

BY F I N [illegible] JR

A lamp rheostat is sometimes required for experimental purposes when receptacles for the lamps are not available Where they are watched sufficiently to avoid any danger from fire Edison base lamps may be held in place by nails thereby overcoming the need of receptacles The illustration shows such an arrangement in which a lamp is held in place on a board by three nails A B C No dimensions are given for the location of the nails as their proper position is very readily obtained by using a lamp as a gage The edge of the board should be about at the junction of the base to the globe as shown See that the nails for holding the various lamps are so located that the globes do not crowd one another The wires are connected to the nail B and to either A or C They are twisted around the nails and may be soldered there to if desired When in use the board should be laid on a table somewhat larger than itself and with the lamps in a horizontal position In case a lamp accidentally becomes loose the table will catch it and prevent its being broken The lamps are inserted by pushing them down ward between the nails A and C and screwing them up until contact is made with the nail B Notice that with certain connections a short-circuit will result if the shell of the base touch the nail B at the same time that it touches C



A SIMPLE LAMP RECEPTACLE

CAPT CODY'S BRITISH ARMY AEROPLANE.

(*Concluded from page 198*)

two-bladed propellers in opposite directions by means of sprockets and chain. These propellers, as noted in our former article, have blades which taper toward the tips, the widest part of the blade being at the hub Another interesting point about these blades (which are made of aluminium) is that the arms which carry them are fastened to the rear or pressure side of the blades. These arms are inclosed by a false face, in order to avoid sharp angles, but there is a high ridge down the face of the blade, which is so great that the blade has in reality a triple curved face. From the cutting edge to the center the camber increases the pitch, then comes the reversal of the curve, where the false face rounds the arm, and finally a renewal of the sharp camber where the false face runs off in to the trailing edge The propellers are said to give a thrust of over 30 pounds to the horse-power

The weight of the Cody biplane complete with the aviator is about 2,000 pounds. Despite the fact that it is such a large machine, it has been designed with a view to ready portability The main planes each divide into three sections, consisting of a central portion 20 feet in length, and two end portions each of 16 feet in length. The poles which support the rear rudder fold back against the planes, and the front rudder bamboos can be readily dismounted The chassis also comes apart, and thus the whole machine can be easily and quickly dismounted for transport Although no test has been made of its speed, this machine because of its powerful motor and efficient propellers, and, especially, because Capt. Cody has attempted to reduce all head resistance to a minimum, is undoubtedly a very fast one. It is probable that it will compete with the Bleriot and Antoinette monoplanes which are to race in England for a $25,000 purse next month

For the details and drawings of the Cody biplane published in this article, we are indebted to the English weekly Flight.

◆

Aviation Abroad.

The second foreign aviation meeting, which was held last week at Brescia, Italy was by no means as successful as the first event at Rheims. The field was very rough, which made landing without breakage difficult, and in addition to this the weather was not always propitious. M Lefebvre, the daring French aviator who piloted a Wright biplane at Rheims was killed at Juvisy on September 7th when his machine plunged to the ground This is the second fatal accident which has occurred with a Wright aeroplane Lieut Calderara, of the Italian army, who also had a bad fall in his Wright machine a couple of months ago, again came to grief when he took Lefebvre's place at Brescia on September 8th, the first day of the meeting Just after starting the aeroplane tipped so badly that one runner struck the ground and was demolished M Bleriot struck a tree and broke his propeller Anzani's propeller also broke while he was attempting to make a test flight. Both the latter accidents were attributed to the unevenness of the ground Curtiss and Bleriot crossed the starting line every day in the 31 mile race for the Grand Prix according to the regulations, but no extended flights were made up to the time of our going to press. It was much too windy on the 10th instant for any flight to be made At Berlin Orville Wright continued to make daily flights. On September 7th he flew for 52 minutes, and on the 9th he made two flights for Crown Prince Frederick He is teaching Capt. Englehardt to operate the machine. At Scarborough Beach, near Toronto, Can., Mr C F Willard last week made two excellent flights out over Lake Ontario with the Curtiss biplane of the Aeronautic Society Each time he started by running down an incline on the shore of the lake, and made a circle from one to two miles in circumference, landing in the water successfully upon floats fitted to the aeroplane. This is the first time a motor-driven aeroplane has been fitted with floats and made to alight without damage upon water

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

SHIRT-COLLAR —J Dorr, New York, N. Y The collar is of the turn-down type, arranged to permit the wearer to conveniently slide the necktie in the collar to the desired position, the necktie not coming in contact with the rear collar button but passing over a flap overlying the collar button and forming an integral part of the turn-down portion, permitting the wearer to draw the collar tight in front by the necktie, causing the collar to appear with a lock front and keeping the top edges close together.

Electrical Devices.

BATTERY-COVERING —G E. Andrews, Providence R I The more particular purpose of the inventor is to provide a two-part covering made of rubber, and provided with means for rendering a battery cell so completely water tight that the cell may be effectively employed where moisture is excessive, or even be totally submerged under the surface of water

SWITCH HOOK-CONTROLLING DEVICE.—M M Kahn, Louisville, Ky In operation, the weighted arm normally rests upon the hook or weight. When, however, the telephone is in use, the arm is thrown backwardly into position, and may be secured in this position by means of the set screw After the telephone has been used, the arm is again turned forwardly into engagement with the hook.

Of Interest to Farmers.

PLANT PROTECTOR.—R. R. Drake, De Land, Fla. In growing some vegetables, and particularly tomatoes, and especially in southern latitudes, great care is necessary in controlling access of the sun's rays to the plants so as to graduate their effect to a certain non injurious degree The north side requires no such protection as the others, but being open it allows free access for setting the plants and for weeding, and otherwise tending them while growing

BEET HARVESTER —M J Ely Oxnard, Cal An object here is to provide a device in which the plow can be raised or lowered and locked in either position so that when the digger is being used and the plow is locked in its lowered position, it cannot be lifted therefrom without lifting the entire weight of the whole frame of the machine together with the wheels and the weight of the driver

THRESHING MACHINE —T S Hayes Bay City Texas The invention has in view a rigid frame arranged at one side of the harvester and adjustable to different elevations above the ground, the frame carrying the harvesting mechanism and braced intermediate its length by the frame of a downwardly and outwardly inclined elevator

Of General Interest.

CARD-INDEX CASE. —E. A Yunge, New York, N Y In this index case it will be impossible to place a card out of its correct position and the invention may be broadly defined as consisting of a card holding receptacle, with the bottom thereof having card-engaging members located in relatively different positions for each card or set of cards the case is to contain and without interruption between adjacent members.

EYE-SHADE.—G E. Henry, Philadelphia Pa. This improvement has reference to eye shades of the kind mounted upon spectacles, the more particular purpose being to support the shade upon the end portions of the spectacles, and also to produce certain changes in construction of the shade and its support, thereby increasing the general efficiency of the device.

Hardware.

SELF HEATING SOLDERING-IRON — A. Hudson Oshkosh Wis The object of the invention is to produce an iron which will operate effectively to produce a thorough vaporization of the liquid as it is admitted to the burner The invention relates especially to the types of irons which are heated by liquid fuel

WIRE STRETCHER.—F Stanlake Owosso, Mich. This invention pertains to improvements in stretchers, and more particularly to that type in which there are employed a ratchet member and a pivoted lever member having dogs in engagement with the ratchet member and having its pivot movable longitudinally of the ratchet.

Heating and Lighting.

HOT WATER HEATER —R. B. Sadler, Richmond Va In the present patent the invention is an improvement in hot water heaters and it has for its object the provision of a simple and effective structure which will be durable in operation and which will not easily get out of order or leak and will produce a maximum heating effect in operation.

BOILER —C E. Chapman Fort Edward, N Y A purpose here is to provide a stationary flash boiler in which the steam dome and water column are removed from and are practically independent of the boiler proper, and wherein the amount of water contained by the boiler from the water column by [illegible] air pressure in the water column over and above the boiler pressure is under complete control.

GAS-LIGHTER.—W D. C. Wright, Philadelphia, Pa. A spark coil and battery cells are disposed in a casing, to which is attached a hollow standard, at the top of which there is a stationary electrode and also a spring electrode, the latter being attached to an electrical conductive rod held in bearings in the hollow stem. The casing is of conductive metal and the rod is in electrical communication with the casing. Means provide for completing the circuits.

Household Utilities.

LIQUID STRAINER — M Arrubarrena, Cienfuegos, Cuba The principal object the patent has in view, is to provide a continuously acting filter for sugar syrup, which may be operated with the minimum of power and readily cleaned. Throughout the whole of the construction, the material used is perforated, and therefore filtration is not arrested at any point.

Machines and Mechanical Devices.

CLUTCH.—J Schneider, Ann Arbor, Mich. In the present patent the invention relates to clutches, and it has for one of its objects the provision of one which will permit of the ready engagement of the drive and driven shafts, with automatic means which will more securely connect the two shafts should there be any slip from the wearing of the parts after the clutch has been thrown into operative position.

CARD-EXHIBITING DEVICE. — A. J Thomas, Hosmer, S. D Means are here provided for conspicuously displaying illustrated postal cards, or cards whereon fancy buttons or like merchandise are placed. The invention affords an apparatus of great capacity and extremely well adapted for the exhibition of cards in large number and of different design, that are brought into view by manual operation of the machine

POT FEEDER FOR TYPE-CASTING MACHINES.—L. A. Sengel, Victoria Texas. In this instance the invention relates to typesetting and type-casting machines, and more particularly to such machines as are employed to cast slugs provided with impression characters, each slug representing the line, or its equivalent, to be printed.

CENTRIFUGAL BOLTING-MACHINE — G Cusson Chateauroux, Indre, France The invention has reference to an apparatus suitable for use in a flour mill as a flour extractor for the different grindings of wheat as an extractor of semolina, oatmeal, or groats as a meal-sifter, and capable also of being used in various industries.

Prime Movers and Their Accessories.

BOILER FLUE CLEANER.—J Wiechmann, Albany, N Y In this case the object of the inventor is to provide a new and improved boiler flue cleaner, arranged to insure a thorough removal of scale and to provide the desired flexibility of the cleaner to readily pass through bent or curved tubes, flues, or pipes.

INDICATOR —C W Snyder Hudson, N Y The improvements are in indicators adapted for use in connection with engines, for making indicator cards to show the variations in the pressure in the cylinder during the movement of the piston. It is especially adapted for use with internal combustion engines.

Railways and Their Accessories.

GRAIN CAR DOOR – P J A Schroon Holstein Iowa. This door is intended to meet the several requirements in loading or unloading grain and can be conveniently manipulated to form openings of more or less extent according to the use to which the car is to be put It may readily be attached to the door of an ordinary car

DUMPING CAR.—T Lawson, New York, N Y This invention pertains to dumping cars admitting of general use, and particularly railway cars of the general type described in a former patent granted to G I King and T Lawson. The object of the present invention is to improve the general construction of the car, and especially of the means for tilting the box and opening the doors thereof

MAIL-BAG CATCHER.—D. W Council, Rutherfordton, N C The object of this patent is to provide a device which may be applied to the car without any changes in the same, which will take the bags from the crane or support already in use, and hold it until it is removed from the holder, and which will deliver the outgoing bag, at the time it receives the incoming one

Pertaining to Vehicles.

VEHICLE-SPRING.—J N Baswell, New York, N Y The invention refers to carriages, road wagons, trucks and like vehicles, and its object is to provide a spring, arranged to yieldingly support the vehicle body and to readily compensate for the variations of the load, without danger of breaking the springs and without requiring the heavy multiple leaf springs now generally employed.

HARNESS.—D. P [illegible], Greenville, S. C. An object in this case is to provide a simple harness for detachably securing a draft animal to a vehicle, by means of which the horse or other draft animal can be readily secured to the vehicle, and which permits the horse to be instantly released in case of necessity without the driver leaving the vehicle.

CARBURETER FOR INTERNAL-COMBUSTION ENGINES.—P. J. [illegible] and E. M. [illegible], 71 Rue du Moulin Vert, Paris, France. The object of the invention is to obtain an additional supply of air in a carbureter, which is automatically operated by the vacuum which is created in the carbureter by the operation of the motor and to permit of varying the proportions of air and of carbureting fluid according to requirements by using the vacuum itself.

Designs.

DESIGN FOR A BADGE.—J W. Gross, Los Angeles, Cal. The badge has the shield form with a beaded border Inside of this the flat surface is ornamented with a clock face at the top placed between the outspread antlers of a deer on whose collar are the capital letters B P O. E. A small flower is on each side of the animal's head at the lower corners.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending

August 31, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Abnormal potential discharging and arc disrupting device, Erickson & Lord ... 933,087
Acid making apparatus, sulphuric, F. J. Falding ... 932,541
Adding machine, J. H. Gleet, Jr. ... [illegible]
Advertising apparatus, C. F. De Soria ... [illegible]
Advertising apparatus for cars, etc., J. Crane, Jr. ... [illegible]
Advertising device, automatic dental, Lavallee & Constantineau ... [illegible]
Air brake appliance, safety railway track, J. L. Boring ... [illegible]
Airship, H. E. & W. D. Le Fevre ... [illegible]
Airship, J. Markle ... [illegible]
Airship, J. A. Rignoe ... [illegible]
Albumen and animal casein and the products therefrom, treating vegetable, F. G. Wiechmann ... [illegible]
Alfalfa cutting machine, D. L. Adelsperger ... [illegible]
Ammonia from coal gases, recovering, F. J. Collin ... [illegible]
Amusement apparatus, H. N. Ridgway ... [illegible]
Annealing furnace with inlet sealed by steam, C. C. Baldwin ... [illegible]
Antiseptic composition containing phenyl acetate, N. Sulzberger ... [illegible]
Apparel apparatus, E. Karnstedt ... [illegible]
Assorting and sizing apparatus, E. W. Johnson ... [illegible]
Atomizer, T. A. De Vilbiss ... [illegible]
Atomizer for perfumes and other liquids, H. Hartmann ... [illegible]
Automatic gate, J. W. Johnson ... [illegible]
Automobile carriage, T. J. Van Pelt ... [illegible]
Bag filling machine, J. L. Dodson ... [illegible]
Bag tie, J. M. Strycker ... [illegible]
[illegible]

Big Money In Drilling
Our customers all over the Country are making from $25 to $75 profit a day with the Cyclone Drill. No business offers such big returns for the money invested.
Contractors, prospectors, well drillers, find the Cyclone Drill more economical, faster and easier to operate than any other
We make Hollow Rod, Cable and Core Drills, to meet every need.
We also make combination machines that will handle any or all of the systems equally well, a machine that will enable you to cover the entire field of drilling
Cyclone Drill
Our Diamondite and Steel Shot Core Drills cut faster and at fraction of the cost of the old diamond drills. We sell Cyclone Drills on an *easy payment plan*. Some of our customers have made more than the price of the machine within one month. Our new traction Gasoline machine—only one made—is of particular value where fuel and water are scarce. Send for our free books on Drilling, and let us know in what branch of the work you are interested.
CYCLONE DRILL COMPANY, 11 Main St., Orrville, Ohio
Chicago Office, 419 Fisher Building

Fire Insurance Rates Too High?
Doubtless. But the rate simply measures the fire loss as a thermometer does the temperature. Rates in America are ten times higher than in some parts of Europe, but—in 1908 the fire loss in America was **238 Millions of Dollars.** This enormous waste was largely preventable. Slipshod methods of construction and criminal carelessness in the use of property bring about this terrible fire loss. It is any wonder fire rates are high in America?
Do you want to help reduce the fire cost and fire insurance rates? THE HARTFORD FIRE INSURANCE COMPANY has published a book on this subject which contains chapters for the Householder, the Merchant and the Manufacturer. It tells each how to reduce the chance of fire in his particular class of property. If all property owners would follow the suggestions of this book the fire waste would be lessened and fire insurance rates would be greatly reduced. The book also gives valuable advice as to how insurance should be written and tells in simple language common errors to avoid. This book may save you thousands of dollars and much trouble, no matter in what company you are insured. It is free.
Send for it at once.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES.

$5 PER DAY PAID to competent automobile drivers. A complete instruction book that will qualify you for these positions will be sent postpaid for 50c. This book tells all about driving and adjusting automobiles, explains all gasoline and automobile troubles. Satisfaction guaranteed or money refunded. Address George N. Pearson, Dept. S, Bala, Pa.

Inquiry No. 8948.—Wanted to buy nickeloid for buttons.

NEWEST BASKET BALL on royalty. Indoors and outdoors. Fascinating, healthy, harmless, skillful game. Popularity greater than "Ping Pong" or "Diabolo" predicted for it. "Frost," 225 Epler Block, Seattle, Wash.

Inquiry No. 8918.—For manufacturers of "Wyitt's Electro-Catalytic Sparking Plug."

A COMPANY IN DALLAS, TEXAS, operating a good foundry and machine shop, and wishing to engage in manufacture of gas and gasoline engines, gas producers, and possibly automobiles, desire to procure the services of a thorough, competent, reliable and experienced man capable of designing and manufacturing this line successfully. Address W. E. Myers, Dallas, Texas, care Olive & Myers Mfg. Co.

PATENTS FOR SALE

FOR SALE.—Patent No. [illegible]. Speed gage for automobiles. So constructed that all vibration of the indicator is obviated. For further information write to J. K. R., Box [illegible], New York.

Inquiry No. 8931.—For the manufacturers of gilt paper.

FOR SALE.—Patent No. [illegible]. Screw driver with joint handle giving auger handle purchase when screw goes hard. Nothing like it on market. H. D. Bartlett, [illegible] N. Marshfield Avenue, Chicago, Ill.

Inquiry No. 8932.—Wanted the address of Worthington Boiler Co.

FOR SALE OR ROYALTY.—Patent just issued on non-slipping self-adjusting clutch. Simple and tight. For further particulars address John Schneider, [illegible] Miller Avenue, Ann Arbor, Mich.

Inquiry No. [illegible].—For parties who manufacture the Western Stump Borer for boring stumps.

FOR SALE.—French Patent [illegible]. Pneumatic automobile spring. For further information, address W. H. Steele, Cohoes, N. Y.

Inquiry No. 8941.—For manufacturers of machinery for making fly screens.

FOR SALE ON ROYALTY.—A new and improved rotary engine, operated by compressed air and steam. Sure seller when merits are known. Canadian patent also for sale. Thos. Jorgensen, Martinez, California.

HELP WANTED

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition, and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The National Co-operative Real Estate Company, Suite [illegible], Marden Building, Washington, D. C.

Inquiry No. 8960.—For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 8966. Wanted the address of the [illegible] Motor Co.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 8969.—Wanted machines that make accordion dress plaiting (steam).

Inquiry No. 8977. For manufacturers of machinery for manufacturing denatured alcohol.

Inquiry No. 8980.—For the address of manufacturers of mortars and pestles that are used by druggists.

Inquiry No. 8987.—Wanted, the manufacturers of the Van Winkle, Woods & Sons, and the Weber power motors.

Inquiry No. 8990.—For information regarding shoes not made of leather but similar to the same and are as durable.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

Inquiry No. 8997.—Wanted the address of the manufacturers of bread or cake boxes.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

Inquiry No. 9009. Wanted the address of the manufacturer of the "Leroh" showcard holder, a device which is held to the outside of a show window by rubber cups.

Inquiry No. 9010. Wanted to buy a "Rector Help-a-Phone."

Inquiry No. 9012. Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

Practical and Instructive Scientific Books

AGRICULTURE.—The New Agriculture. By T. Byard Collins. 12mo.; 374 pages; 106 illustrations. [illegible]

A popular outline of the many changes which are revolutionizing the methods of farming, and the habits of farm life. It is one of the most practical treatises on the subject which has ever been issued.

ALCOHOL.—Industrial Alcohol. Its Manufacture and Uses. By John K. Brachvogel. 8vo., 528 pages; 107 illustrations. [illegible]

A practical treatise based on Dr. Max Maercker's "Introduction to Distillation" as revised by Drs. Delbrück and Lange comprising raw material, malting and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat, and power production, a statistical review and the United States law.

AMATEUR MECHANICS.—Home Mechanics for Amateurs. By George M. Hopkins. 12mo., 370 pages; 326 illustrations. $1.50

This is a thoroughly practical book by the most noted amateur experimenter in America. It appeals to the boy as well as the more mature amateur. Holidays and evenings can be profitably occupied by making useful articles for the home or in the building of small engines or motors or scientific instruments.

AMUSEMENTS.—The Scientific American Boy. By A. Russell Bond. 12mo.; 317 pages, 340 illustrations. $2.00

This is a story of outdoor boy life suggesting a large number of diversions which, aside from affording entertainment will stimulate in boys the creative spirit. In each instance complete practical instructions are given for building the various articles.

COMPRESSED AIR.—Compressed Air. Its Production, Uses, and Application. By Gardner D. Hiscox. 8vo. 665 pages; 540 illustrations. [illegible]

The most complete book on this subject. It treats on its physical and operative properties, and is written by an expert. Taken as a whole it might be called an encyclopedia of compressed air.

DIES.—Their Construction and Use for the Modern Working of Sheet Metals. By Joseph V. Woodworth. 8vo., 384 pages; 505 illustrations. [illegible]

A most useful book and one which should be in the hands of all engaged in the press working of metals, treating on the designing, constructing, and use of tools, fixtures and devices, together with the manner in which they should be used in the power press, for the cheap and rapid production of sheet metal articles.

ELECTRICITY.—The Standard Handbook for Electrical Engineers. Written and compiled by a Staff of Specialists. Second edition, corrected. 12mo. 1285 pages, 1250 illustrations. Bound in flexible morocco. $4.00

A new pocketbook consisting of twenty sections each written by a specialist of engineering experience and containing the latest data and information regarding standard electrical practice.

ELECTRICITY.—Electrician's Handy Book. By T. O'Conor Sloane. 761 pages; 556 illustrations. Handsomely bound in red leather pocket-book style. [illegible]

This work is intended for the practising electrician who has to make things go. Although the principles of electricity and magnetism are treated, the greater part of the book is devoted to practical handling of machinery, details of construction, and computations such as will be encountered in every-day practice.

GAS ENGINES.—Modern Gas Engines and Producer Gas Plants. By R. E. Mathot. 8vo., 314 pages; 152 illustrations. [illegible]

A practical treatise setting forth the principles of gas engines and producer design, the selection and installation of an engine, conditions of perfect operation, producer gas engines and their possibilities, the care of gas engines and producer gas plants, with a chapter on volatile hydrocarbon and oil engines.

GAS ENGINES.—Gas, Gasoline, and Oil Engines. Including Producer Gas Plants. By Gardner D. Hiscox. 8vo., 442 pages; 351 illustrations. [illegible]

A complete book on the subject for gas engine owners, gas engineers, and intending purchasers of gas engines, treating fully on the construction, installation, operation, and maintenance of gas, gasoline, kerosene and crude petroleum engines, with special information on producer and suction gases.

GAS ENGINES.—Gas Engine Construction. By H. V. A. Parsell and A. J. Weed. 8vo., 304 pages, 145 illustrations. [illegible]

A practical treatise describing the theory and principles of the action of gas engines of various types, and the design and construction of a half-horse-power gas engine, with illustrations of the work in actual progress, together with the dimensioned working drawings giving clearly the sizes of the various details.

HEATING.—Practical Steam and Hot Water Heating and Ventilation. By Alfred G. King. 8vo., 402 pages; 304 illustrations. [illegible]

An original and exhaustive treatise, prepared for the use of all engaged in the business of steam, hot water heating, and ventilation. The standard and latest book published. Describes all of the principal systems of steam, hot water, vacuum, vapor and vacuum-vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation.

HYDRAULICS.—Hydraulic Engineering. By Gardner D. Hiscox. 8vo., 315 pages; 305 illustrations. [illegible]

A practical work treating on the production, power, and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits, the horse-power of falling water, turbine and impact water wheels, wave motors, centrifugal, reciprocating, and air-lift pumps, etc.

INDUCTION COILS.—The Design and Construction of Induction Coils. By A. Frederick Collins. 8vo. 295 pages; [illegible] illustrations. [illegible]

This work gives in minute details full practical directions for making eight different sizes of coils varying from a small one giving a [illegible]-inch spark to a large one giving [illegible]-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the descriptions are written in language easily comprehended.

LATHES.—Modern American Lathe Practice. By Oscar E. Perrigo. 8vo.; 424 pages; 314 illustrations. [illegible]

A new book describing and illustrating the very latest practice in lathe and boring mill operations, as well as the construction of and latest developments in the manufacture of these important classes of machine tools.

MAGIC.—Stage Illusions and Scientific Diversions, including Trick Photography. Compiled and Edited by Albert A. Hopkins. 8vo.; 568 pages; 420 illustrations. [illegible]

This very interesting volume is [illegible] to the amateur as well as [illegible] professional and amateur [illegible] all explained in detail [illegible]

MECHANICAL MOVEMENTS.—Mechanical Movements, Powers, and Devices. By Gardner D. Hiscox. 8vo.; 400 pages; 1,800 illustrations. [illegible]

This is a collection of 1,800 different mechanical motions and appliances, accompanied by appropriate text, making it a book of great value to the inventor, the draftsman, and to all readers with mechanical tastes.

MECHANICAL APPLIANCES.—Mechanical Appliances, Mechanical Movements and Novelties of Construction. By Gardner D. Hiscox. 8vo.; 396 pages; 990 illustrations. [illegible]

This book, while complete in itself, is in fact a continuation of the author's "Mechanical Movements, Powers, and Devices." The author presents to the reader information regarding nearly [illegible] devices for producing motion or accomplishing mechanical results.

SPECIAL OFFER: These two volumes sell for [illegible] each, but when they are ordered at the same time from us, we send them prepaid to any address in the world, on receipt of [illegible].

PATENTS.—Practical Pointers for Patentees. By F. A. Cresee. 12mo.; 144 pages. [illegible]

Containing valuable information and advice on the sale of patents and elucidation of the best methods employed by the most successful inventors in handling their inventions. It gives exactly that information and advice about handling patents that should be possessed by every inventor who would achieve success.

PHYSICS.—Experimental Science. Elementary, Practical, and Experimental Physics. By George M. Hopkins. In two volumes. 8vo., 1,100 pages; 918 illustrations. Cloth, [illegible]. Half morocco, [illegible]

This book treats on the various topics of physics in a popular way and describes with rare clearness and in detail the apparatus used, and explains the experiments in full, so that teachers, students, and others interested in physics may readily make the apparatus without great expense and perform the experiments without difficulty.

PLUMBING.—Modern Plumbing Illustrated. By R. M. Starbuck. 392 pages 10½ x 7¼, 55 full-page engravings. [illegible]

A comprehensive and up-to-date work illustrating and describing the drainage and ventilation of dwellings, apartments, and public buildings, etc. The very latest and most approved methods in all branches of sanitary installation are given.

PUNCHES.—Punches, Dies, and Tools for Manufacturing in Presses. By Joseph V. Woodworth. 8vo., 483 pages, 702 illustrations. $4.00

This work is a companion volume to the author's other work entitled "Dies, Their Construction and Use." It might well be termed an encyclopedia on die making, punch making, die sinking, and sheet metal working.

RECEIPTS.—The Scientific American Cyclopedia of Receipts, Notes and Queries. Edited by Albert A. Hopkins. Containing 15,000 selected formulas. 8vo., 734 pages. Cloth, [illegible]. Sheep, [illegible]. Half morocco, [illegible]

Over 15,000 selected receipts are here collected, nearly every branch of the useful arts being represented. The alphabetical arrangement with abundant cross references makes it an easy work to consult. It has been used with equal success by chemists, technologists, and those unfamiliar with the arts, and is a book which is useful in the laboratory, factory, or home.

REFERENCE BOOK.—Scientific American Reference Book. Compiled by Albert A. Hopkins and A. Russell Bond. Containing 50,000 facts. 12mo.; 516 pages, illustrated. [illegible]

This book deals with matters of interest to everybody. It contains 50,000 facts, and is much more complete and more exhaustive than anything of the kind which has ever been attempted. It is indispensable to every family and business man. It is a book for every-day reference—more useful than an encyclopedia, because you will find what you want in an instant in a more condensed form.

STEAM ENGINE.—Modern Steam Engineering in Theory and Practice. By Gardner D. Hiscox. 8vo., 487 pages, 405 illustrations. [illegible]

This is a complete and practical work issued for stationary engineers and firemen, dealing with the care and management of boilers, engines, pumps, superheated steam, refrigerating machinery, dynamos, motors, elevators, air compressors, and all other branches with which the modern engineer must be familiar.

TELEPHONE.—Telephone Construction, Installation, Wiring, Operation, and Maintenance. By W. H. Radcliffe and H. C. Cushing, Jr. 16mo.; 171 pages; 125 illustrations. [illegible]

A practical book intended for electricians, wiremen, engineers, contractors, architects, and others interested in the installation of telephone exchanges in accordance with standard practice. Intricate mathematics are avoided, and all apparatus, circuits, and systems are thoroughly described. Selected wiring tables, which are very helpful, are also included.

TOOLS.—American Tool Making and Interchangeable Manufacturing. By Joseph V. Woodworth. 8vo.; 535 pages; [illegible] illustrations. [illegible]

A complete practical treatise containing a [illegible]

TOOLS.—Modern Machine Shop Tools. By W. H. Vandervoort. 8vo.; 555 pages; 673 illustrations. [illegible]

A new and fully illustrated work describing [illegible]

WIRING.—Electric Wiring, Diagrams and Switchboards. By Newton Harrison. 12mo.; 272 pages; 105 illustrations. [illegible]

This work is a thoroughly practical treatise on electric wiring in all its branches [illegible]

Any of the above books will be sent postpaid on receipt of price.

Our complete catalogue of scientific and technical books sent free on application.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863 will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co Inc 361 Broadway New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway New York.

The Multiplication of Power

There is no higher efficiency in the world than that of the American business man

The multiplication of *power* in a business man—if he has the ability within him—depends upon the *increased number* of people whom he can *by personal contact*, interest in his purposes.

He does this by telephone and the multiplication of *the telephone's* usefulness depends on the *increased number* of persons whom he can reach.

In 1890 the Bell System had 200,000 subscribers telephones in use As late as 1899—ten years ago—it had only 500,000

To-day it has 4,400,000—one for every twenty persons in this country—and is increasing at the rate of 500,000 a year

Has the vast development of industries since 1890—the greatest period of advance in the world's history—*when America has advanced faster than all the rest of the world*, been the force that has built up this great, unified, efficient telephone service, or

Has the increased ability of the American business man to bring people to him from every locality, far and near, *over the Bell Telephone System*, been the cause of the multiplication of his power and his principality?

Whichever the cause and whichever the effect the advancement of one is inseparably linked with the advancement of the other

The business man's Bell Telephone, with its long distance and emergency advantages, is his most precious asset next to his capital itself

The Bell Long Distance Telephone means as much to the home as it does to the office It is the most marvelous convenience of modern times—if not all time—added to home life

The American Telephone and Telegraph Company
And Associated Companies

Every Bell Telephone Is a Long Distance Station

Solders and Soldering

Safety Insurance is Better Than Revolver Risk

Any kind of a revolver shoots—sometimes when you want it to, sometimes when you don't. The man who buys a revolver without an absolute assurance of its safety, in action or at rest, takes chances every time he holds the weapon in his hands. When *you* buy *your* revolver, buy a *safe* revolver. And when you're buying, fix this one fact in your mind—the

HOPKINS & ALLEN
Triple Action
SAFETY POLICE
Is Safe Because Its Safety Is Inbuilt

This Hopkins & Allen Triple Action is the real safety action. This is what the Triple Action means: The instant you pull the trigger the hammer cocks, then lets drive at the firing pin straight and hard, the second it hits the firing pin, the instant the shot is fired, the third movement then lifts the hammer up and above the firing pin, away above it, out of all possible contact with it. There it lodges securely, safely—firm, fixed and immovable against a wall of solid steel. The weapon will not, *cannot* fire again unless you actually pull the trigger all the way back.

The new Army Grip gives a strong, firm handhold and adds to the effectiveness of the revolver. 32 and 38 calibre, 4 inch barrel, nickeled finish $9.50; blued finish $10.00. For sale at all good hardware and sporting goods stores, but if your dealer does not have it we will send one post paid on receipt of price.

Send for our Gun Guide and 1909 Catalog and learn more about the Triple Action Safety Police. This catalog also shows our other lines—the most complete range of high grade, low price firearms made anywhere in the world. Write for it today. *It's Free.*

BUY THIS HAYNES AT $2,000

LET THE OTHER FELLOW DO THE TRYING OUT

"I want a Haynes—a Standard machine. My experience with three different makes of machines that have been owned in three years by my brother and me convinces me that a *Standard* car is none too good. Let the other fellow do the trying out."

The above is an abstract from a letter just received from a Battle Creek man who has evidently had his fill of experimental cars.

And his experience is undoubtedly the experience of thousands of other owners who have economized on their first car or two.

Repeated letters of this kind make us seriously doubt as to whether any buyer of a so called cheap car *believes* when he buys it that he is getting the kind of a car he really *wants*.

He may get value received *for the amount invested* but unless he gets a smooth running easily controlled full power car and one that is *economical to maintain* he is not likely to excuse the lack of these qualities on the ground that he has only a small amount invested.

And it is at this point that the strong appeal of this Model 19 Haynes comes to the buyer.

For here is a car with an internationally known name selling at hundreds of dollars less than is asked for any other car with similar reputation and only a little above the price asked for scores of cars *built merely to sell*.

It affords the buyer an opportunity to economize on the first cost of his car and also to be *absolutely sure of his purchase*—a combination that is as lacking in so-called cheap cars as it is, in another way, in overly expensive ones.

HAYNES

Everything about this Model 19 is in keeping with the Haynes reputation for superior construction.

It has a distinctly classy appearance. It has a motor that has made Haynes cars famous for their smooth-running quality and their unusual power, it has the much talked-of Haynes clutch, it has Timken roller bearings throughout. It is luxuriously upholstered, and it has an abundance of room.

It has everything you want or expect in an automobile.

And it puts within reach of every automobile buyer the kind of car that every buyer *prefers*, namely a car of *established reputation*, a *standard* car of *known quality*.

Whether you buy this car or not you owe it to yourself to investigate it.

A *Haynes car at $2,000* is certainly too good a proposition to pass up if you are in the market for an automobile.

Mail attached coupon for booklet giving full details of this car and important information as to *wherein* it is superior to other cars.

THE "WASH" OF AN AEROPLANE.

Those of our readers who have sat in a racing shell or stood at the wheel of a racing yacht will remember how troublesome is the "wake of a competitor whether it takes the form of the wash of his sculls or of the disturbance of the air as it sweeps from the leach of the mainsail of a weatherly yacht that is eating out to windward some distance ahead In the case of two racing yachts that are thrashing it out on the same tack in a struggle to windward there is a certain relative position of the two in which the disturbance of the air caused by its passage over the sails of the leading yacht will prove exceedingly troublesome to the second boat especially if she be but a few lengths astern and sailing close to the wake of the other When this occurs, there is nothing for it but to put about on the other tack and so get clear of the interference

With the rapid development of mechanical flight, the remarkable extent of which was shown so clearly in the recent brilliant performances at Rheims it has become evident that the wash, or interference which is inconvenient to a sailing yacht, may become positively disastrous to that yacht of the air the aeroplane It was not until the Rheims contests that an opportunity was presented to determine the effect of one aeroplane upon another when in meeting or overtaking they passed in rather close proximity It is quite possible that the question of interference had never occurred to the aviators at Rheims, but it is certainly a surprising fact that the existence of such interference and its evidently serious character as shown when several machines were in the air at once should not have excited more attention both at the time and in subsequent export discussions of the Rheims contests

When such a large body as an aeroplane spreading several hundred square feet of surface and weighing from a quarter to half a ton is driven at fifty miles an hour by propellers that are revolving at from 1 000 to 1 200 revolutions per minute it is certain to leave in its wake a complicated series of aerial cross currents, whirlpools, and vortices Now, judging from the description of eyewitnesses of the Rheims races, the behavior of the aeroplanes when they swept into rather close proximity to one another, indicates that these artificially-created wind storms were present and that they seriously affected the equilibrium of any aeroplane that came within their influence The "wash" from propellers, driven as in the case of Bleriot's monoplane by an 80-horse-power engine and the air waves set up by the passage of his planes must be very serious indeed certainly the air will not regain its equilibrium until long after the machine has swept by

Two notable instances of this interference occurred when several aeroplanes were in the air together During one race when Farman was rapidly overhauling opponents who were flying at the same level, he encountered the wash of the machines and his own aeroplane was thrown into rather violent oscillation Before he could pass it was necessary to make a wide detour to the right or left or swing up to a higher level into undisturbed air On another occasion when Latham flying high overtook a competitor who was traveling at a lower level it was noticed that his own aeroplane made a sudden dive, as though drawn downward by the suction of the machine below him

We attach no little importance to a question which must become increasingly serious as the number of flying machines is multiplied, and the favorite lines of travel become populous with these mechanical birds of the air "Leeway," as the sailors call it, will become even more necessary to the air yacht than it is now to the sailing yacht Woe to the aviator who, flying low with scant clearance between himself and the ground is overtaken by some aeronautical scorcher who sweeps up from behind, and with the characteristic snort of triumph whirls onward giving him his aerial dust. Happy for him if he recover his rudely-disturbed equilibrium at the expense of a broken wing and not of a broken neck Perhaps after all we have been a little too "previous" in felicitating ourselves upon the unlimited room that will be afforded for flight through the air, evidently the clearance demanded by our sixty-mile-an-hour aeroplane must be measured by something far wider than the stretch from tip to tip of the planes or the length from head to tail

THE RETURN OF HALLEY'S COMET

The announcement by Prof Max Wolf that he has discovered Halley's comet will be received with interest and with surprise by every astronomer throughout the world—with interest because not a little credit redounds to the Heidelberg astronomer, when it is considered how much this honor has been coveted, and with surprise because the historic comet has made its appearance nearly four months before it was expected

Halley's comet is unique because it was the first celestial body of its kind which was mathematically subjugated to the law of gravitation and because its history is to a large extent the history of astronomy In 1682 a comet was observed by Newton, Halley and others On examining the circumstances of its motion, Edmund Halley who was Newton's intimate friend and who did perhaps more than any other astronomer of his day to popularize the idea of gravitation computed its orbit on the supposition that it was parabolic Comparing his results with the observations of previous comets for which purpose it was necessary to calculate their orbits from the necessarily imperfect measurements of earlier times, he found that in 1531 and 1607 comets had appeared which followed so nearly the same path that he ventured to assert its identity with them and to predict its return within a period of about 75 years. Knowing that he would not live to witness the event because of his advanced age he left a plea for recognition which reads Wherefore if it should return according to our predictions about the year 1758 impartial posterity will not refuse to acknowledge that this was first discovered by an Englishman

In the year 1758 the French astronomer Clairaut took up the task of computing the perturbations which the comet would probably have experienced since its last appearance because of the influence of the two great planets, Jupiter and Saturn An extremely laborious calculation showed that the comet would have been retarded about 100 days by Saturn and about 518 days by Jupiter, and accordingly he announced to the Academy of Sciences near the end of the year 1758 that the comet might be expected to pass its perihelion about April 13th of the following year and that owing to various defects in this calculation, there might be an error of a month either way The comet was actually discovered by an amateur George Palitzsch, on Christmas day 1758 thereby justifying Halley's brilliant conjecture adding a new member to the solar system and raising the hope (to be later amply fulfilled) that in other cases also the motions of comets might be reduced to rule. Thus at one fell stroke the dreadful divinity that once hedged a comet the badge of pestilence of war, and of death, was swept aside for all time

Since Clairaut's day Halley's comet has been made the subject of much mathematical inquiry The French astronomer Pontécoulant carried the calculation of the perturbations back to 1531 and recently Messrs. Cowell and Crommelin of Greenwich have traced the comet back beyond the Christian era The result of these computations has been to prove that Halley's comet undoubtedly appeared in 1066, and was promptly regarded by William the Conqueror as an omen of victory for his English invasion, and that it is the same which is depicted on the Bayeux tapestry In 1378 and 1456 it appeared again Constantinople was besieged by the Turks in 1456, and the comet was regarded by the Mohammedans as a favorable sign because of the crescent-shaped tail. Christendom was so alarmed at the simultaneous apparition of the Turk and the comet that a Papal Bull was promulgated against both In a measure, therefore, the history of Halley's comet is the history of civilization.

The problem of predicting the return of such a body as Halley's comet is one of considerable difficulty If the sun and comet alone existed in space, the path of the comet could be determined easily There are also planets to be considered, and these have a marked perturbing effect.

So variable are the features of the comet, that in all the recorded instances of its return the descriptions never quite tally In 1066 it created universal dread throughout Europe In 1145, according to the Chinese, it had a tail 10 degrees long In 1222 it is spoken of as a fine star of the first magnitude with a large tail. In 1456 it occupied a space nearly 70 degrees in length, and spread terror throughout Europe during the month in which it was visible On the other hand, in 1531 and 1607 it does not appear to have been so conspicuous, for its tail was only 7 degrees long. In 1682 the comet attracted little attention except among astronomers, the tail being 12 to 16 degrees long. This apparent waning of the comet led to the fear that in 1758, the year of its first predicted return, it might be so faint as not to be visible at all In truth, the tail was not visible until after perihelion, and was then inconspicuous because at its brightest it was seen against bright twilight In 1835 the comet was visible to the naked eye during the whole of October, and its tail varied from 20 to 30 degrees in length So marked have been the fluctuations, that there is some question whether the comet will be as magnificent in 1910 as it was in 1546 or whether it will be as insignificant as it was in 1607

Halley's comet never reappears with clock like regularity The change in period from one revolution to the next in some cases has amounted to more than two years. The longest revolution so far recorded was that from 1222 to 1301—79 years and 3 months. The shortest round is the one now being accomplished in a little less than 75 years and 5 5 months. This extreme range of over four years in the orbital period renders necessary the most careful and laborious calculation of the effect of the attraction of all the planets upon the comet. It is indeed marvelous that mathematicians have come so near to predicting the exact date of perihelion at previous appearances. The best calculation hitherto made was that of Pontécoulant, who was only two days out of the way, an achievement which is not likely to be outdone by mathematicians of our time In 1864 Pontécoulant published the results of his calculation of the present return and placed it early in May 1910 a result with which the observations of Cowell and Crommelin agree. Their reservation that possibly the comet may be at perihelion a few weeks sooner is amply justified by Wolf's early discovery At present the comet is about 250 000,000 miles away from the earth At the beginning of November its distance should be not more than 165 000 000 miles

It is certain that if May 10, 1910, is the date of perihelion the comet will be disappointingly near the sun so that the solar glare will rob it of its principal glories.

THE SELDEN PATENT CASE.

The decision which has been handed down in the United States Circuit Court upholding the Selden patent will be received with mingled surprise and disappointment. We are probably safe in stating that few patent lawyers ever believed in the validity of the patent If the defendants carry out their intention of appealing, it is not impossible that the decision will be reversed

The Selden patent was granted on November 5th 1895, to George B Selden Originally filed on May 8th 1879, its final allowance was postponed until the birth of the automobile industry by delaying the filing of amendments The chief claim in issue was "the combination with a road locomotive, provided with suitable running gear, including a propelling wheel and steering mechanism, of a liquid hydrocarbon gas engine of the compression type, comprising one or more cylinders, with suitable fuel receptacle, a power shaft connected with and arranged to run faster than the propelling wheel, an intermediate clutch or disconnecting device, and a suitable carriage body adapted to the conveyance of persons or goods, substantially as described" In other words, George Selden claimed all of the essential features of a modern automobile Every one of the features embodied in this claim was individually old If they were patentable in combination as a road carriage, was a new result produced? We doubt it. The internal-combustion motor was known before Selden's day So were power shafts connected with and arranged to run faster than the shafts or wheels which they propelled So were intermediate clutches or disconnecting devices between shafts running at different speeds.

Thus far, the patent has consumed nine years of litigation, almost half a million dollars, and 60,000 folios of testimony to provide material upon which to base a disappointing decision The Selden patent expires on November 5th, 1912 It may be doubted whether its validity will be finally settled before it expires, if an appeal is taken.

That the patent was ever respected by the automobile industry is due largely to the fact that it was cheaper to pay the slight royalty demanded by its owners than to contest its validity

ENGINEERING.

It seems that unless the new cyanamide industry should create a big demand there is a possibility of an overproduction of calcium carbide. It is estimated that the yearly demand is 192,000 tons. According to Mr Pitaval, the French output last year was 26 000 tons as against a maximum capacity of 50,000 tons. He estimated that the carbide factories of the world have an aggregate of 367,000 horse-power

According to official Canadian railway statistics for the year 1907, the United States has a population of 381 for each mile of railway, and Canada 289 France has 1,590 for each mile of railway, and the United Kingdom 1,821 In India there are 10 119 people for each mile of railroad. In the United States there are 13.61 square miles of territory for each mile of railway, in Canada 161 8 square miles, in the United Kingdom 5 29 square miles, and in France 8 46 square miles for each mile of railway

The proposed Forth and Clyde Canal has been criticised in the House of Commons on the ground that its cost of $20,000 000 will be out of all proportion to its subsequent value Admiral Campbell in reply lays emphasis upon its great strategic value as affording a quick means of transit of warships from the North Sea to the Atlantic and *vice versa* In view of the recent construction of a powerful naval base on the Firth of Forth the importance of such a canal outside of its commercial value has been greatly increased

In view of his classic experiments of twenty years ago and his construction of a gigantic aeroplane the announcement that Sir Hiram Maxim has built a new biplane cannot fail to arouse much interest in the world of aeronautics. The most valuable feature of his work was the determination of the best form of propeller by means of a whirling arm Outside of the fact that his new motor (which, together with the rest of the machine has been built by Messrs Vickers Sons & Maxim) is extremely light in proportion to its power no particulars regarding the machine have been made public

The proposed method of driving ships by the combination of steam turbine and motors, which at first was received rather coldly is now beginning to receive the attention to which we consider it to be well entitled In a recent discussion of the subject in Cassier's Magazine the advantages of the system for cargo boats are stated as follows More cargo can be carried, coal consumption is less there is greater propeller efficiency in rough weather and less propeller racing, and the vessel is not totally disabled if the rudder or a propeller shaft is disabled The disadvantages are that the first cost of the ship is greater and that a more skillful staff is required

At the recent meeting of the British Association for the Advancement of Science at Winnipeg interesting papers were read by Sir John Thornycroft on 'Hydroplanes or Skimmers' by Mr C B Smith on The City Hydro-Electric Plant" of Winnipeg, by Lieut-Col W P Anderson, Chief Engineer of the Department of Marine on Improvements in the Navigation of the St Lawrence', and by Col. G W Goethals chief engineer and chairman of the Isthmian Canal Commission on "Engineering and Construction Features of the Panama Canal" The latter was considered the most important paper and will appear in full in the Association's Proceedings, only one paper in each section so appearing

Two of the largest lighters afloat have recently been launched by Messrs. Rennie of Greenwich England They are entirely constructed of steel, 112 feet long 30 feet beam, and 11 feet 9 inches deep with a draft when lifting 500 tons of 10 feet. They are divided for 66 feet of their length by a well on either side of which are six separate water-tight compartments any or all of which can be quickly flooded for balancing, while they may be expeditiously cleared by a powerful steam pump. The quarters for captain and crew are forward, and boiler and engine room aft The lighters have been built to the order of the Mersey Dock and Harbor Board, and are intended primarily for raising sunken vessels and similar objects

The Metropolitan District Railway of London and its associated underground lines are subjected to a destructive wear of the rails which was not present in the days of steam operation One form of this wear is known as "battering," which results in hollows that develop at distances of from two to three feet apart. It is generally found on the inner rail on curves. Corrugation is a well-known phenomenon on electric roads and constitutes one of the most puzzling features of rail wear under electric traction This trouble is no doubt largely due to the fact that part of the weight of the motors is carried directly on the axles without the intervention of springs and that the center of gravity of the motor car is much lower than that of the steam locomotive. A partial remedy has been found in the use of high silicon rails, which show an increased life of about 30 per cent over rails of the standard composition.

ELECTRICITY.

An electrolytic process for the production of bleaching solution is used by the Amazon Knitting Mills of Muskegon, Mich., by which the cost of bleaching is said to be less and the results obtained much more uniform

Japan is falling in with the general movement for the electrification of railways and the Hachioji Kafu line of the Japanese middle district railway is to be electrified Fifteen motor cars have already been ordered from the Osaka Railway Carriage Company

The Canadian Department of the Interior has recently been estimating the available water power of Dominion streams, and concludes that there is over twenty six million horse-power in accessible localities, of which only half a million has been hitherto developed The largest power is on the Hamilton River in Labrador where 9 000,000 horse-power is available, the Canadian part of Niagara Falls coming second.

The Electrical World has an interesting discussion of Prof Marks's article on the price of electric service It is pointed out that on account of the difficulty of cheaply storing electrical energy the consumption of any individual user is as important a factor in the cost of serving him as the operating cost, and that it is therefore reasonable for some sort of standing charge based on his estimated or measured demand to be made in addition to a service charge based on operating cost.

Machinery aggregating 10 000 horse-power and other equipment to the total value of $400 000 is now on its way to Dawson City where Klondike mining operations are expected to be facilitated by the provision of electric power An English company has taken over the present power station the only coal mine in the district and the local telephone system Water power is available for part of the year but is complicated by floods at one season and drought at another The present power plant uses wood fuel largely the local supply of which is becoming exhausted and considerable economies are expected from use of coal screenings hitherto wasted at the new company's power house which will be erected at their mine

The city of Glasgow Scotland whose record for an efficient and economical municipal tramway system is well known has also a remarkably well-conducted electric light and power supply department according to figures recently received for the past year's working In spite of a decrease in income of $38 000 due to reduced charges for current increasing use of economical metallic filament lamp and general trade depression an actual increase in available profit balance of $14 000 has been made The aggregate horse-power sold is 29 500 an increase of 6 000 over the previous year and 1 232 new consumers have been added Eighteen million units out of thirty three sold were for power purposes bringing in on the average 1½ cents per unit

The experiments, which we described about a year ago with apparatus for the destruction of harmful moths by means of a combination of electric light and a suction blower have been repeated with great success at Zittau in Germany The beam from a search light mounted on the roof of the municipal electric plant is played upon the forest several miles distant and the moths come fluttering up the beam in swarms to where the intake of a powerful suction blower is concealed below massed arc lamps. The moths are drawn in by the suction and exhausted into a wire net cage which is removed as often as filled As much as 140 pounds weight representing some 400 000 moths has been destroyed in this way in one night

It is not generally known that the disturbances in Persia reports of which from London have occupied much space in the press of late, pass over the longest telegraph circuit in the world The telegraph operator at Teheran "speaks' directly to his colleague in London, 4 000 miles away, by wire, automatic repeaters taking the place of operators at ten points on the route The first repeating station from London is at Lowestoft, where the message is carried forward 200 miles by cable under the North Sea to Emden Hanover, where it is again automatically repeated, stations at Berlin Warsaw, Rouno Odessa Kertch Sukhum Kaleh, Tiflis, and Tauris flash it instantaneously without human intervention, the operator at Teheran being the first to handle it since it left London The line is continued to India, but in no other place is there so long an automatic circuit.

Mr. George H. Cove of Somerville Mass has a solar thermo-battery which is claimed to produce enough current in ten hours' sunlight to supply thirty tungsten lamps for three days. The apparatus consists of a frame of violet glass, like a large window, below which a number of metallic plugs are set in an insulating material. One end of each plug is constantly exposed to the sun while the other is shaded and cool, and the rays permitted to pass by the violet glass set up a reaction in the special alloy used, causing a constant flow of current to the storage batteries.

SCIENCE.

The famous lion of Lucerne appears to be doomed. The entire face of the sandstone rock in which the figure is carved is falling to pieces, and in spite of every effort on the part of the local authorities, the lion is crumbling away and becoming disfigured

The Duke of the Abruzzi has made a new record in mountain climbing The highest ascent hitherto made in the Himalayas the scene of the Duke's exploit, was by the Norwegians Muradas and Robertson, who reached a height of 7,300 meters (more than 23,725 feet) The Duke mounted Bright's Peak which is 7 600 meters (above 24 700 feet) in height This peak is in the Godwin Austen group

Scientists now have placed at their disposal the highest meteorological and astronomical observatory on the American continent It is situated on the top of Mount Whitney California 14 000 feet above sea level Realizing the value for effective and progressive astronomical and meteorological work of an observatory far above the clouds and free from dust and smoke near great cities, the Smithsonian Institution decided to build a suitable laboratory on Mount Whitney Now that the observatory is opened it will be used by scientists of the Smithsonian Institution and by others to make observations. The Smithsonian will permit the building to be used by any scientist gratuitously

We have already made the statement in these columns that the Lick Observatory under W W Campbell sent an expedition to the top of Mount Whitney for the purpose of spectroscopically comparing the atmospheres of the moon and Mars the object being to settle once and for all the mooted question of Martian water Inasmuch as the moon has an atmosphere which if not non-existent is at least inappreciable the comparison of its spectrum with that of Mars's atmosphere should prove conclusively whether or not there is any water on Mars A telegram has been received at Harvard College Observatory from Prof Campbell in which he states that together with Dr Albrecht he compared the spectra of Mars and the moon and detected only a little water vapor on Mars The bands which were measured were of equal intensity and very faint A reply from Prof Lowell will naturally be looked for with some interest It will be remembered that Mr Slipher of Prof Lowell's staff has stated that he discovered spectroscopic evidence of water on Mars.

The common impression that the soils of the United States are wearing out and that the crop yields are on the decrease is declared to be erroneous by Prof Milton Whitney chief of the Bureau of Soils The results of his investigation will be published in the next bulletin of the Department of Agriculture In summing up Prof Whitney says that a careful study of the data appears to justify two conclusions—first that the productivity of the newer agricultural soils of the United States is not decreasing Individual farming deteriorates and soils wear out but as a whole it seems probable that we are now producing more crops per acre than formerly The cultivation of the land has been more intelligent the principle of rotation of crops has been better observed and in latter years, a more careful use of fertilizers has been made In addition we must recognize the increase in farm animals and stock the improvements in such by selection and breeding and the increased population which is forcing attention to more intensive methods of cultivation

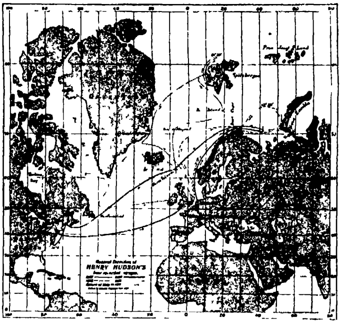
An effective method of freeing the air of rooms from dust and germs is especially desirable for primary schools children's hospitals surgical operating rooms and spinning mills The method hitherto in use consists in supplying a current of air which has previously been purified more or less completely Richet has devised a simple method of purifying the air confined in a room by causing it to circulate continuously through an apparatus which retains the dust and microbes. The apparatus is simply an electric fan which revolves in a vertical cylinder and produces a current of nearly 2 cubic feet per second Water or some other liquid drips from a 3-quart vessel at the rate of 1 quart per hour, upon the blades of the fan from which it is projected by centrifugal force in fine drops to the wall of the cylinder The impurities of the upward blast of air are caught by the spray which then trickles down the cylinder to a large basin in which the whole apparatus is set. Richet employed glycerin and soap solution but the air can be purified very well by a spray of water alone. One hundred thousand microbes estimated by the usual methods were thus collected in three hours from the air of the laboratory The dried organic matter collected in the same interval weighed about 1 grain, and the mineral matter ¼ grain The same apparatus can evidently be employed for the chemical purification of the air by substituting appropriate solutions—cuprous chloride for the removal of carbon monoxide, potash or soda for carbon dioxide, etc.

HUDSON AND HIS EXPLORATION OF THE HUDSON RIVER.

The name of Hudson has been given to the Hudson River not by any means because he was its original discoverer but because he was the first navigator to explore the river throughout its navigable length and leave behind a detailed account of his voyage It will therefore be fitting to preface the present record of Hudson's voyage by a brief reference to the discoveries of earlier explorers

After the return to Spain of the remnant of Magellan's expedition in 1522 it began to be well understood in Europe that a vast ocean must separate the New World and Asia, and the early navigators forthwith began to search for some route by which they could avoid the long journey from Europe to Asia by way of the southern seas and find a direct route in more northerly latitudes The explorers sought eagerly for a northwest passage gradually laying their courses farther and farther up among the ice floes of the Arctic regions The eastern coast of North America was carefully searched and the tiny caravels of those days were sailed into the mouths of great rivers in the hope that they would prove to be straits or channels opening through into the Western Ocean Among these early explorers was Lucas Vasquez d Allyon who tried for a passage by the James River and through Chesapeake Bay in 1524 In 1525 *Estevan Gomez sailed down the coast from* Labrador to Florida making a record of Cape Cod Narragansett Bay and successively of the mouths of the Connecticut the Hudson and the Delaware rivers Early in 1524 Giovanni da Verazano who was born in 1480 at Florence crossed the Atlantic with a single ship and a crew of fifty men He sighted Cape Fear N C and coasted north to latitude 50 deg About the last of April 1524 the Dauphine as Verazano's craft was called arrived off a low point of land now known as Sandy Hook where seeing an inviting harbor Verazano sailed into the roadstead *The ship's boat* was manned and rowed through the Narrows into the Upper Bay where a hasty survey was made of its islands and inlets and the mouth of the noble river which flowed into it He speaks of the river as a very great river (*una grandissima riviera*), and the name Grande River was used by some of the leading map makers of Europe during the sixteenth century When the Dutch took possession of this part of the country the name Groote was substituted for the Italian term Henry Hudson was no doubt induced to explore the Grande River by a letter from Capt John Smith who wrote that it was a strait connecting with the western sea which in those days was believed to lie not very far from the Atlantic seaboard

Of Henry Hudson the man we know comparatively little and that little is comprised within the years 1607 and 1611 He was born in or near London but of the exact date of his birth there is no certainty His first appearance is on April 19th 1607 when with eleven companions he is found partaking of Holy Communion in a little church in London prior to embarking on his first recorded voyage Our last sight of him is when he passes from view among the mists of Hudson Bay on June 22nd 1611 turned adrift with a few companions by the mutinous crew of the Half Moon No authentic portrait of the man exists He came of a seafaring family had a wife and children and evidently belonged to a prominent family He made four recorded voyages the first second and fourth under English auspices and the third under the Dutch In 1566 Parliament incorporated "The Fellowship of English Merchants for the Discovery of New Trades which was better known as the Moscovy Company and it was in their employ that Hudson on his first voyage made an effort to reach China by passing between Greenland and Spitzbergen At latitude 81 deg 30 min he was checked by the Arctic ice and returned home This voyage lasted from April 23rd to September 15th 1607 The second voyage in 1608 lasting from April 22nd to August 26th had the same object in view This time he endeavored to pass between Spitzbergen and Nova Zembla After reaching latitude 75 deg 30 min he was driven back by the ice In 1609 he entered the service of the Dutch East India Company, and made the voyage which resulted in the exploration of the Hudson River His last voyage made under the auspices of the Moscovy Company commenced on April 17th, 1610, had for its object a search for a northwestern route to the Pacific Ocean through what is now called Hudson's Strait and it was here in the following June that Henry Hudson John Hudson, and seven others mostly sick and disabled were set adrift by the mutinous crew in an open boat, with a gun some powder and shot an iron pot some meal and a chest of carpenter's tools The ultimate fate of the great explorer whether he died of starvation or drowning or was frozen to death is a matter of pure conjecture.



The voyage of 1609 during which he discovered the Hudson River is shown by a full black line

MAP SHOWING HENRY HUDSON'S FOUR RECORDED VOYAGES, 1607-1610.

On the 8th of January 1609 a contract was made between 'the Directors of the Dutch India Company of the Chamber of Amsterdam' and Mr Henry Hudson Englishman assisted by Jodocus Houdius who was to act as interpreter In the Dutch copy of the contract preserved at The Hague Hudson's Christian name is three times spelled Henry and he signed the document in the same way so that in the opinion of the Hudson Fulton Celebration Commission, as he was an Englishman, it is a mistake to call him Hendrik

The Half Moon set sail from Amsterdam April 4th 1609 with a crew of eighteen Dutch and English sailors The object of the voyage as per the contract was to seek a passage to the north of Nova Zembla and by an easterly course to reach what is now the Pacific, in the latitude of 80 deg. On May 5th he rounded North Cape, but, baffled by the ice and by the discouragement of his crew, he determined, instead of returning home, to sail direct to the coast of America at the latitude of 40 deg., where he hoped to find a northwest passage by a strait which his friend, Capt. John Smith, in the letter sent to him from Virginia, informed him led into the Western Ocean somewhere between New England and Virginia. On July 18th he cast anchor in a harbor on the coast of Maine. He touched at Cape Cod, sailed to a point one hundred miles south of Chesapeake Bay, and then turned northward again and entered Delaware Bay *Finding* the river unnavigable, he ran back to the ocean and sailed up the coast, and on September 2nd was off the New Jersey shore and anchored probably off what are known as the Navesink Highlands to the south of New York Bay On the following day the 'Half Moon" let go her anchor inside of Sandy Hook The week was spent in exploring the bay with a shallop, or small boat, and 'they found a good entrance between two headlands" (*the Narrows*) "and thus entered on the 12th of September into as fine a river as can be found."

The log of this voyage was kept by Robert Juet who was probably the mate of the 'Half Moon" It is written in the quaint English of that period, and is entitled "The Third Voyage of Master Henry Hudson, toward Nova Zembla, and at his return, passing from Farre Islands to New-Found Land, and along to Fourtie-Foure Degrees and Ten Minutes, and thence to Cape Cod, and so to Thirty Three Degrees and along the coast northward to Fortie-Two Degrees and one Halfe, and up the river neere to Fortie-Three Degrees '

In his passage up the river, Hudson made progress according as wind and tide were favorable, the time from sundown to sunrise being always spent at anchor On Monday the 14th he passed through a "very high and mountainous" country probably the Highlands. On the following day, mention is evidently made of the Catskills, when the log records that they "came to other mountains which lie from the river side" On Saturday, the 19th, the little ship had reached the northerly limits of its trip and anchored off what is probably now the northern section of the city of Albany Further exploration of the river was made in the shallop, in the expectation of finding deeper water beyond the shoals This was a vain hope however, and the conviction must finally have come to the heart of the intrepid adventurer that once again he was foiled in his repeated quest for the northwest passage On Wednesday the 23rd, the Half Moon' started on her return trip down the river *On the 29th she was at the northern entrance to the* Highlands having reached "the edge of the mountaines or the northermost of the mountaines." Detained by a heavy gale until October 1st, Hudson weighed anchor on that day and reached Stony Point Finally, on Friday, the 2nd, the Half Moon' cast anchor off "a cliffe that looked of the colour of a white greene," which is considered to have been undoubtedly "the green serpentine outcrop" at Castle Point, Hoboken

Evidently the 'Great River" made the same pleasing impression upon Hudson as it has done on the many millions who have voyaged between its banks in the intervening three centuries Says he "It is as pleasant a land as one need tread upon. The land is the finest for cultivation that I ever in my life set foot upon." With a few exceptions, he found the native Indians to be friendly disposed. Dressed in skins and with the characteristic decoration of feathers, wearing copper ornaments on their necks and carrying bows and arrows, they smoked large red or yellow copper tobacco pipes. To the little ship they brought tobacco, dried currants, grapes, corn, pumpkins, and beaver and otter skins, which they bartered for knives, hatchets, and trinkets The country appears to have been quite populous with the Indians, who lived in dome-shaped huts, built of saplings and covered with bark. They existed chiefly on corn, which, together with beans, was dried for their winter use Fish and birds also formed part of their diet, and mention is made of salmon, mullets, rays, and sturgeon. At the various places where Hudson landed he was usually received [illegible] and with no little ceremony It is evident that Hudson's treatment of the Indians was kindly, and the [illegible]

The raised superstructure forward contains the quarters for the crew Below the bowsprit, furled on its yard, is the curious square sail known as the blind sail" The sailors are dressed in the costume of 1609

THE REPLICA OF THE "HALF MOON", PHOTOGRAPH TAKEN JUST BEFORE SHE WAS SHIPPED TO AMERICA.

to have a beneficial and lasting effect on the subsequent history of this State.

It was while at Albany that Henry Hudson decided "to trie some of the chiefe men of the countrey whether they had any treacherie in them", and accordingly he "tooke them down into the cabin and gave them so much wine and aqua vitae that they were all merrie, and one of them had a wife which sate so modestly, as any one of our countrey women would do in a strange place In the end one of them was drunke'

Not always was the intercourse of this convivial character After the return of the "Half Moon" to the lower harbor, and when John Coleman and four others were exploring in the shallop, they were attacked by the natives, and Coleman was killed This was on September 6th. Other conflicts occurred on the 9th and the 15th of September, and on October 1st, the log records how an Indian who had climbed up the rudder to the cabin window was caught stealing and shot. The following day the Indians attacked in force, and were driven off with a loss of eight or ten killed On the 4th of October the 'Half Moon" sailed down the harbor and out to sea, and "on the seventh day of November," according to the log 'being Saturday by the grace of God the Half Moon' safely arrived in the range of Dartmouth in Devonshire in the year 1609"

THE "HALF MOON"

When the replica of Henry Hudson's "Half Moon' was lifted by the floating crane at the Brooklyn navy yard from the deck of the "Soestdyk,' on which she was brought over from Holland, and lowered into the water, there was a general expression of surprise at her diminutive appearance for she was actually no larger than a small harbor tug On rowing over to the craft and going aboard, however, it was at once evident that what she lacked in size, she more than made up in general staunchness and strength of construction Bluff of bow and high in the poop, as was the fashion in naval architecture of three hundred years ago, built of heavy oak timbers, and planked and decked with the same material, the Half Moon was well calculated to stand the buffetings of long deep-sea voyages. Moreover her underwater model is such with its long clean run, that, although it must have been slow work beating to windward it is certain that with the wind free and sheets started the little craft must have been good for say six knots, and possibly—under favorable circumstances—a little more than that. All the same in view of the diminutive size and exceedingly cramped quarters of the Half Moon," one is filled with admiration for the daring and resourcefulness of the men who struck boldly to the northwestward in such a cockle shell of a boat, on voyages of many months duration and in a quest for a northwest passage which must needs lead them on to dangerous coasts and amid treacherous shoals, of which there was no chart, beacon or buoy to give them friendly guidance

The 'Half Moon must be seen to be appreciated Of 80 tons displacement, she is only 80 feet in length over all, 63 feet on the waterline 16 feet 11 inches beam, 10 feet 1 inch molded depth and 7½ feet draft of water She was built by a committee of patriotic Dutch citizens, who provided the necessary funds, her plans being drawn from original sketches and documents prepared by the late instructor of shipbuilding in the Dutch navy In the parade up the Hudson River she will be manned by officers and a crew from the Dutch ship of war 'Utrecht," all dressed in the quaint costumes of three hundred years ago Forward is the raised forecastle, the sleeping place of the crew, provided with five berths. Forward of this and below the bowsprit is the galley, an extraordinarily exposed and wet position, where, says tradition, the sailors were placed for punishment. At the after end of the boat on the main deck was the position for the steersman, whose head projected through the steeply-sloping quarter deck above him and was protected by a curious canopy In front of the steersman were a compass, a sand glass, and a log glass. Upon the main deck and covered in by the steeply-sloping deck, known as the quarter deck, is the captain's cabin. Under his berth, in an artistically bound chest, are the books which comprised the captain's small library Upon the diminutive table is a sea chart, a faithful reproduction of the one existing copy, mentioned by Shakespeare, which is in the British Museum On the table also is a copy of the contract with Hudson for his notable voyage, dated January 6th, 1609 Here also are the primitive dividers and measuring scales for plotting the course The cabin contains a Jacob's staff the primitive sextant with which Hudson determined with a fair amount of accuracy, his latitude All of these articles are faithfully copied from prototypes in the Netherland Museum. Above the captain's cabin is a smaller one for the accommodation of the mate, and above this is the lofty poop deck

From a naval constructor's point of view, one of the most curious things about the 'Half Moon" is the exaggerated upward slope of the after part of the main deck and of the quarter and poop decks above it, the effect of which was to give great elevation to the poop Curious indeed to our eyes is this lofty structure but it must have been an excellent position from which to navigate the ship About four feet below the main deck is the 'tween deck or the orlop deck where the head room is so limited that the crew must have at times performed some of their duties on all fours Here are the two old fashioned cannon the primitive kitchen and berth for the cook a bread room and berth for the steward and a gunner's room in which the powder was stored Below is the hold in which were stored the provisions, drinking water cable and cargo The Half Moon carries three masts and a bowsprit Below the latter is a curious square sail known as the 'blind sail On the foremast are a foresail and a topsail on the mainmast a mainsail and a main topsail and on the mizzen is a lateen sail The shrouds stays, spars and in fact the whole of the rigging, standing and running is exceedingly strong and well set up The old Dutch East India Company, whose chief office was in Amsterdam, placed on all its vessels the initial letter of the port from which they sailed This accounts for the large letter A on the stern of the 'Half Moon" Other signs painted on the vessel are a starry heaven a comet, planets, and a half moon Below these are the name of the vessel and the arms of Amsterdam and of the company

Note the steel cradle in which the boat was carried on the deck of the "Soestdyk." The transfer was made by the floating crane

"HALF MOON" BEING LIFTED FROM STEAMSHIP TO DOCK AT THE BROOKLYN NAVY YARD

View looking aft, showing the lofty poop containing the steersman's position and the cabins for Hudson and his mate

REAR VIEW OF THE "HALF MOON."

◆

THE FOUR PERIODS OF HUDSON RIVER HISTORY

For the lovers of history none of the pageants of the Hudson Fulton Celebration will equal in interest the great parade of Tuesday September 28th which will tell the story of the past three hundred years of Hudson River history in a procession of over half a hundred floats representing the successive periods of Indian Dutch English and American occupation

Henry Hudson during his exploration found the river occupied by two great branches of the aboriginal Indians the Algonquins at the mouth and in the lower river and the powerful league of the Iroquois, or Five Nations, at its head With a few slight exceptions Hudson's reception was friendly and both he and his crew appear to have treated the Indians with consideration It is certain that such conflicts as occurred were insignificant in comparison with the battle fought between the Canadian Indians under Champlain on the shores of Lake Champlain and a party of Iroquois Indians—a conflict which occurred only a few days before Hudson sailed into New York Harbor The contrast between the French and the Dutch and English treatment says the Hudson Fulton Commission led to the formation of the famous Covenant Chain of friendship between the Indians and the latter and prevented the French from ever obtaining a permanent foothold in the State of New York

The Dutch who succeeded the Indians as owners of what is now New York State, were in 1609 the leading commercial nation of the world and Amsterdam from which Hudson set sail was its leading port The interest aroused among the early Dutch traders by Hudson's voyage led to the erection as early as 1613 of traders huts along the Hudson River The first permanent settlements were made at Fort Orange (Albany) in 1624 and at New Amsterdam (New York) two years later The colonial history of New Netherland began with the landing on Manhattan Island of Peter Minuit as the first Governor-General in 1626 Under New Netherland was included the territory between the Connecticut and Delaware rivers The English took possession in 1664 surrendered to the Dutch in 1673 but once more gained possession this time destined to be permanent in 1674

Henceforth New Netherland was to be known as New York, New Amsterdam as New York city and New Orange as Albany but the Dutch origin of New York is still commemorated in such names as Brooklyn Harlem and Staten Island Regarding this momentous change, the Commission is of the opinion that the merger of the Dutch and English *régimes* was accomplished more completely and naturally than a change of jurisdiction could have been made between almost any other two nations in the world for the Dutch were more closely allied to the old Anglo-Saxon stock from which the English are descended than any other living European people Intense rivals in commerce England and Holland had worked hand in hand for years for the liberties of Europe and there were radical bonds of sympathy between them which contributed materially to the progress of the colony of New York

The American or United States period began of course with the Declaration of Independence on July 4th 1776 The geographical position of the Hudson River, which forms part of the great highway of travel from the Atlantic seaboard to the Great Lakes and Canadian territory rendered it strategically of the very highest importance and, therefore the main object of contention between the opposing forces The British realized that if they could establish complete possession of the Hudson Valley they would cut the colonies in two and by establishing a route of communication between Canada and New York they would be able to defeat the colonies in detail The vast range of incidents connected with the Hudson River Valley has rendered it necessary for the Commission to confine the floats to the representation of events more immediately connected with New York city

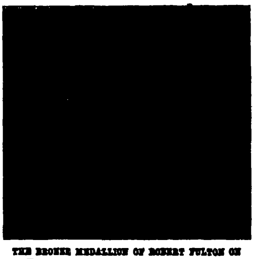
FULTON AND HIS LIFE WORK.

The forthcoming festivities commemorate the first complete exploration of the Hudson River by Henry Hudson and the inauguration by Robert Fulton of successful commercial steamboat navigation on its waters. Hudson was not the first navigator to see the Hudson River, and neither Robert Fulton himself nor the Commission which has organized and carried through the celebration has ever claimed that Fulton was the original inventor of the steamboat It is rarely that a complete invention leaps full fledged from the brain of any one man Almost invariably it is the product of the disconnected labors of separate individuals each of whom contributes his quota to the ultimate result Three men above all others—Symington on the Forth and Clyde Canal Fitch on the Delaware and Fulton on the Hudson River—will be forever associated with the invention of the steamboat and it is because Robert Fulton combined with his fine engineering sense a large executive and commercial instinct, and was backed by the financial and political influence of Chancellor Livingston that he was able not only to put a practical steamship afloat on the Hudson River but to establish the infant enterprise as a permanent commercial success

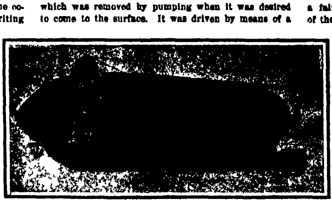
Fulton was born in Little Britain Lancaster County Pennsylvania in 1765 As a boy he showed a decided gift for drawing and mechanics to which was joined an unusual facility for mathematical calculations. At seventeen years of age he went to Philadelphia to take up the study of portrait and landscape painting and mechanical drawing In this he must have shown considerable ability, for at the age of twenty-one he had saved sufficient means to purchase a home for his widowed mother in Washington County In the following year he went to England to study art under his distinguished compatriot Sir Benjamin West who subsequently in 1792 was elected president of the Royal Academy That Fulton was an artist of no small attainment is shown by the character of the work which has survived him and by the fact that his portraits were exhibited at the Royal Academy and at the Society of Arts in Great Britain His own portrait, painted by his brush which now hangs in the rooms of the American Society of Mechanical Engineers in New York is an excellent piece of work and shows distinctly the influence of the master under whom he studied

From a painting by Benjamin West in possession of Fulton's grandson, Robert Fulton Ludlow, of Claverack, N Y.

ROBERT FULTON; 1765-1815.



THE BRONZE MEDALLION OF ROBERT FULTON ON HIS MONUMENT IN TRINITY CHURCHYARD.



Built of copper and iron; driven by a hand crank and propeller; was submerged by admitting water, air was replenished from a tank of compressed air, remained under water 5 hours with three men aboard.
Fulton is the undisputed inventor of the first successful submarine He antedated the present submarine boat by 100 years and demonstrated by successful feats before officials, first of the French and later of the English navy, the practical character of his vessel.

FULTON'S SUBMARINE THE "NAUTILUS."

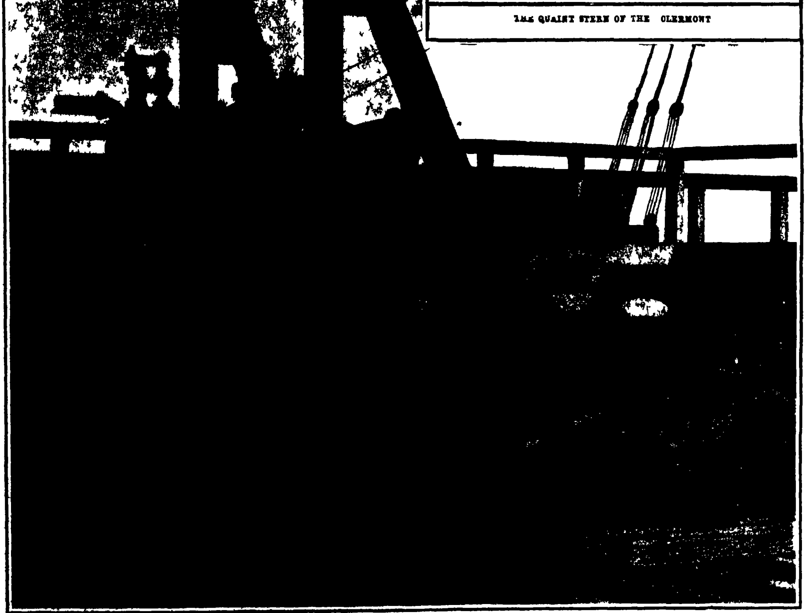
An artist by profession Fulton was an engineer and inventor at heart Benjamin West's influence coupled with his own charm of personality and undoubted social gifts brought him into touch with many leading men in England notably the Earl of Stanhope, whose interest in mechanical and physical science is well known On September 30th, 1793, Fulton wrote to the Earl offering to make known to him his scheme for moving ships by steam and his plan for an inclined plane for the operation of canals In the same year also he invented a mill for sawing marble and other stone and actually had one in operation near Torbay Devonshire His interest in steam navigation at this time is shown by a letter to Boulton & Watt dated November 4th 1794, asking what would be the cost of a steam engine, "which is designed to be placed in a boat The letter was written from Manchester where he met young Robert Owen subsequently known as the distinguished social reformer Fulton interested Owen in his plans for the more rapid and cheaper excavation of canals, and they became copartners in his inventions Meanwhile he was writing a Treatise on Canal Navigation' which appeared in 1796 In 1797 he went to Paris where he obtained two French patents for panoramas A lasting evidence of his work in this direction is to be found in the Rue des Panoramas and the Passage des Panoramas in the French capital Here he lived with the American Minister Joel Barlow of whom he painted an excellent portrait now owned by his descendant Robert Fulton Ludlow of Claverack N Y It was during his residence in Paris that he began to turn his genius for invention almost exclusively to the field with which his name was to be so honorably associated His first efforts were directed to the invention of means for prosecuting submarine warfare He invented a system of torpedoes operated by clockwork, and devised methods of attack which were wonderfully similar to those that were used with such disastrous effect in the late Russo-Japanese war He proposed to float down upon the enemy two such torpedoes tied together by a line, which, being intercepted by an enemy's ship would swing around, strike her sides, and explode His most effective work in this field was the construction of a practical submarine or "plunging" boat, called the Nautilus" This vessel, 6 feet in diameter and 20 feet long, was built of iron and copper and in general outline resembled the modern submarine It was provided with a sail for surface navigation, which could be folded back upon the boat when diving. To submerge the boat, water was admitted, which was removed by pumping when it was desired to come to the surface. It was driven by means of a propeller through a man-operated crank wheel, from which power was transmitted through bevel wheels to a propeller shaft running through the center of the boat. The steering, operation of the pump, and the raising and lowering of the sail, were all accomplished from the interior by the methods shown in the accompanying engraving. Fulton made an exhibition on the Seine, descending with one man, remaining twenty minutes below the water, and coming successfully to the surface. At Brest, in June, 1801, he descended with three men to a depth of twenty five feet, and remained below for one hour, the air being renewed from a reservoir of air under high pressure. On another occasion he attacked a specified boat in the harbor, attached one of his torpedoes, and blew the boat to pieces. This occurred in August, 1801 The significance of these exploits is enhanced when we bear in mind that the experiments above referred to were made to demonstrate to Napoleon I the value of Fulton's invention for attack upon the English fleet. His plan was to build steamboats which were to act as tugs to tow the vessels containing Napoleon's army of invasion across the English Channel, and while the steamboats were to afford Napoleon an opportunity to strike a blow upon land with his army, Fulton's system of submarines would enable the French navy to strike an equally telling blow by sea As the French government failed to accept Fulton's submarine and torpedo inventions, he subsequently returned to England and laid his plans before the British government Mr Pitt, the Prime Minister, was favorably impressed, and Fulton was given an opportunity to attack a brig which was anchored off Deal in the English Channel He launched a torpedo, and by completely destroying the vessel demonstrated to naval and military officers and to a large concourse of spectators the success of his invention. The British government however, for obvious reasons, did not wish to encourage the development of submarine warfare, for they realized its great potentiality They offered Fulton a considerable reward if he would suppress his plans forever This he refused to do, saying to the committee that waited upon him "I will never consent to let these inventions lie dormant, should my country at any time need them."

Fulton, again a resident in France realizing that he had failed to interest either government in his system of submarine warfare, turned to his favorite scheme, and bent his energies to the development of a practical steamboat. He made application to the French government, filing a description and plans of his boat, which have been preserved in the archives of the Conservatoire des Arts et Métiers, Paris. The wide study of what had been done and was then being attempted in the development of the steamboat with which Fulton prepared himself, is shown in these plans, and the reader is directed to the illustration of the boat in the chapter on 'Steamboats Prior to the Clermont," which appears on page 221. The drawing is especially valuable for the light which it throws upon the "Clermont," of which the original drawings have disappeared The date of the letter to the French Commission was January 26th, 1803 Fulton built a small boat, in which he placed his boiler and engine, but on the eve of his demonstration before the Commission, during a heavy wind, the craft, unable to carry its burden, broke in two, and the wreck sank to the bottom of the river The engine, which was presumably the one ordered from Watt, seems to have come through the disaster unharmed, for Fulton immediately built another boat, 66 feet long by 8 feet beam, and in August, 1803, made a fairly successful trial in the presence of members of the Institute and a crowd of onlookers. In spite of this demonstration, Fulton was doomed to disappointment, for the French government failed to take up his invention But his star was now in the ascendant. The wheel of fortune took a turn in his direction, when Robert R Livingston was sent to France to act for the United States in the matter of the Louisiana Purchase. This able man, who had himself already given much study to, and made several experiments in, the development of the steamboat, was quick to see the excellence of the Fulton plans, and became from that time on his ardent associate and never-failing backer "Fulton had genius, and Livingston had the genius to perceive it", and out of the combination of interests thus formed, there was to emerge four years later that curious but capable little craft, the "Clermont"—practically identical in design, and the lineal descendant of the boat which steamed successfully on the

THE CLERMONT'S TRIAL TRIP: SEPTEMBER 14TH, 1909.

DECK VIEW SHOWING FLYWHEELS OUTSIDE HULL

THE QUAINT STERN OF THE CLERMONT



With the exception of the eccentric valve gear, and starting and stopping mechanism which were modernized in accordance with government requirements to insure safe handling during the water parades, this replica is an exact copy of the original of 1807.

The main parts of the engine were built by Watt in England in accordance with Fulton's order of August [illegible], 1803, which called for "a cylinder of [illegible] power [illegible] effect [illegible] a 4-foot stroke, the valves and movements for opening and shutting them, the air-pump piston and rod, the condenser with its [illegible] and air pump." The A frame and guides, the cross-head, the bell-crank lever with its connecting rods to cross head and crank wheels, the crank wheels, paddle wheels and shaft, and the flywheels and shaft with gear for driving the same, were all Fulton's own design, and the arrangement was well adapted for keeping the weight low in his very narrow boat with its small margin of stability. In the original engine the valves were probably operated by a vertical reciprocating rod carrying pins which engaged the valve tripping devices.

(Drawn on board the replica of the "Clermont" by the artist of the SCIENTIFIC AMERICAN.)

THE ENGINE OF THE "CLERMONT"

river Seine Preliminary to our description of the Clermont it is well to make it clear that Robert Fulton is entirely free from any charge of plagiarism It has been asserted that because Fulton inspected the work both of Symington on the Clyde and Fitch on the Delaware and was familiar with Fitch's plans as left in charge of Aaron Vail U S consul at L'Orient, France, it was from these sources that he derived the design of the Clermont ' Now, while it is true that Fulton was in touch with these men and their work and probably saw their steamboats in operation there is nothing in the design of the 'Clermont" to indicate that her hull and the general arrangement of her engine were not the design of Fulton himself On the contrary there is abundant written evidence that the form of the boat and the connections from the cylinder to the paddle wheels were Fulton's. This is said with due appreciation of the fact that Fulton went to Boulton & Watt at Birmingham England for the essential parts of his engine They were the foremost engine builders of their day and it was a wise step on Fulton s part to order the cylinder, condenser and air-pump from a first class firm Both Fitch and Symington it is true, designed and built their own engines throughout but this fact does not invalidate Fulton s claim to be considered as the naval architect of the 'Clermont —a boat which was quite unlike any other that had been built and that was so well designed as to prove a thorough commercial success.

Designed by Fulton for the United States Navy launched in 1814 and completed shortly after his death Length 156 feet beam, 56 feet depth 20 feet, paddle wheel 16 feet diameter, engine cylinder, 4 feet diameter, 4 feet stroke, speed, 4½ knots.

THE "DEMOLOGOS"; THE FIRST STEAM WARSHIP.

While Fulton was yet in Paris and a few days before the trial of his boat on the Seine, he again wrote to Boulton & Watt asking them to build him an engine, which be no doubt intended for the boat that he had in mind to build on his forthcoming return to America On the date of August 6th, 1803 his letter says Will you be so good as to make me a cylinder of a 24 horse-power double effect, piston making a 4 foot stroke? Also the piston and piston rod the Valves and movements for opening and shutting them, the air pump piston and rod, the condenser with its communications to the cylinder and air pump The bottom of the cylinder cast in form as in the drawing and the dispositions of the parts as near as possible as they stand in the drawing The other parts can be made at New York The situation for which this engine is designed and the machinery to be combined with it, will not admit of placing the Condenser under the cylinder as usual' The drawing which accompanied this letter showed the condenser placed forward of the cylinder and not underneath it, as was the practice in the Boulton & Watt engines. Mr H H Suplee who has probably given a more thorough study to this phase of the subject than any other investigator is of the opinion that Fulton wished to place his cylinder directly upon the floor of the boat in order to keep its weight as low as possible. We are inclined to agree with him for the original beam of the Clermont which was only 13 feet rendered her laterally very unstable Furthermore the boat on the Seine which doubtless formed the basis of the design of the Clermont" shows the condenser separate from the cylinder There can be no doubt, after reading the Boulton & Watt letter, that Fulton had the outlines of the Clermont" engine clearly in his mind and its general similarity to the engine of the boat on the Seine is strong evidence that the "Clermont's engines were at least as to their general plan and connections original with Fulton On the other hand the drawings which accompanied Fulton's patent of 1809 show the condenser placed beneath the cylinder a construction which has been followed in the replica of the engine

In drawing the plans it was found that, since the replica of the 'Clermont would have a considerable number of people aboard during the festivities parades, etc., it would be necessary to depart somewhat from the original plans, in order to comply with the requirements of the government inspectors and secure a reliable boat, suitable for the purposes of the Commission Hence, in the interests of historical accuracy, it is advisable to note that the motive power departs in some respects from Fulton's original design, although in the main it is a faithful reproduction. This is particularly true of the eccentric, valve gear, cut-off and starting and stopping devices, and it takes only a glance at our drawing to see that these parts belong to a later period, and are practically similar to those now in use on walking beam engines In the drawings of the boat on the Seine the valve gear and the air pump are shown to have been operated by levers and quadrants Probably Fulton used the "tappets and tappet rod," which were current practice for working the valves in Boulton & Watt engines Another change is in the boiler, which in the original "Clermont" was built of copper and carried a pressure of probably not more than three to five pounds above the atmosphere. In the "Clermont" of 1907, the boiler, in order to meet the government requirements, is built of steel, and carries twenty pounds pressure With these exceptions in mind the visitor to the Clermont' may be satisfied, both as regards the hull and the engines that she looks very much as she did on her first memorable trip up the Hudson Fulton s design, if we consider the crude condition of the art in those days, is creditable and it is a noteworthy fact that if we raise the bell-crank lever above the cylinder, we have an engine which is remarkably like the walking-beam engine of the present day Fulton, however, wished to keep his weights low in the boat, and the plan adopted is admirable for this purpose Two connecting rods from the crosshead are coupled to a bell-crank A-shaped pair of levers, from the top of each of which a connecting rod transmits the motion to a pair of crank spur wheels upon the inboard ends of the paddle-wheel shafts. In order to carry the engines over the dead centers, Fulton provided a pair of fly wheels which were carried upon separate counter-shafts, rotated by means of pinions secured at their inboard ends The air pump and feed pump are operated through connections from the bell-crank levers, as shown

This view shows the engine B driving paddle wheel C in a central waterway, the boiler A and the massive wooden side protection E, 5 feet in thickness

MIDSHIP SECTION OF THE "DEMOLOGOS."

The armament consisted of twenty 32-pounder guns. The plans provided also for two 100-pound submarine guns for attacking the enemy below the water-line.

GUN DECK OF THE "DEMOLOGOS."

About the correctness of the design of the replica of the hull of the "Clermont," there can be no doubt whatever The plans, drawn by Frank E. Kirby and J W Millard, are based upon a letter of Fulton's, which reads "My first steamboat on the Hudson River was 150 feet long, 13 feet wide, drawing 2 feet of water bow and stern 60 degrees", and upon the second enrollment of the "Clermont," on file in the New York Custom House, which describes the vessel as having "one deck and two masts," and gives her dimensions as 149 feet length, 17 feet 11 inches breadth, and 7 feet depth The enlargement in beam is due to later changes which were found necessary to increase the vessel's stability The "Clermont," as originally designed, had therefore a long narrow hull, with parallel sides, a V-shaped bow, and a stern which was V-shaped at and below the waterline, but above the water was carried out with a square overhang. This form was decided upon by Fulton as the result of towing experiments with models which he carried out himself, and he seems to have been of the decided opinion that this was the best form to secure the desired speed. She was provided with a limited amount of sail, of which, at least on her first trip, she seems to have made but little, if any, use. The paddle wheels, 15 feet in diameter were uncovered, and consequently, if any breeze were blowing, the passengers were pretty well drenched with water

Let it not for a moment be imagined that the public of that day had the least appreciation either of the genius of Fulton or the momentous character of the work he was doing. When, on Monday, August 17th, the little craft cast loose from her moorings near the old State's Prison, which stood on the square now bounded by Washington, West 10th, West, and Charles Streets, many of the thousands that lined the shore of the river had come to deride 'Fulton s Folly', and he made his preparations for the start to the accompaniment of jeers and catcalls At 1 o clock the hawser was drawn in, the throttle was opened, and then, amid the curious hush which immediately fell upon the multitude, the side wheels began to turn, and with Fulton at the helm the "Clermont" moved slowly out into midstream and headed north for Albany Skepticism gave way to approbation and delight, and amid thunders of applause the 'Clermont" moved slowly up the river, and was finally lost to sight in the upper reaches of the river At 1 o'clock on Tuesday the little vessel tied up at Clermont Dock, the landing for Chancellor Livingston s place, having covered the 110 miles from New York against the wind at an average speed of 4 6 miles an hour Resuming the journey at 9 o'clock on Wednesday morning, the "Clermont" reached Albany, 40 miles distant at 5 P M., the running time for the whole distance having been 32 hours, which gave an average speed of a little over 4½ miles per hour

We have shown in another chapter how phenomenal was the development of steam navigation on the Hudson River as inaugurated by this eventful trip, a development in which Fulton took a leading part. In 1812 he put his first ferryboat in commission, although to Stevens must be given the credit for having started a ferry to Hoboken in the previous year The boat, which was double-hulled, made her landings at a hinged, floating bridge, to which she was guided by lines of piling. Fulton was thus the originator of our present system of ferryboats. In 1810 we find him before President Madison explaining his models and plans for torpedo warfare In March, 1814, Congress authorized the construction of a steam war vessel to be built from Fulton's plans. This, the first steam warship in the world, was constructed with a double hull. Its dimensions were: Length 156 feet, breadth 56 feet, depth 20 feet. The paddle wheel, 16 feet in diameter, was driven by an engine, whose cylinder was 48 inches in diameter by 5 feet stroke As will be seen from our drawing, the sides of the "Demologos," as she was called, were strengthened by massing heavy timbers, until a thickness of five feet was reached She mounted twenty 32-pounder guns on the gun deck. Fulton, who was present at the launching of the vessel on October 29th, 1814, did not live to see her completed, indeed, it was his devotion to the work of her construction, which led him to spend many hours on her deck in the winter time, when he was troubled with a heavy cold, that brought about his death, which occurred February 23rd, 1815, at his home in what is now Battery Place. He was buried in the Livingston vault on the south side of Trinity Church, and to the northwest of the monument and tablet erected to his memory by the American Society of [illegible] [illegible] in [illegible]

Correspondence.

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN

The search for truth is said to be often of more benefit than its attainment, and I am glad to see that a solution of the problem is beginning to emerge out of darkness, thanks to Mr Eckles's letter in your issue of August 21st, although it only lifts a corner of the curtain.

He proves what I have thought all along that people are far more closely related than is generally supposed, but there is another side to the problem he does not touch.

Consider the five or six distinct races of mankind, and the different nations of the world, such isolated people as the Japanese, Chinese, South Sea Islanders, Eskimo, Thibetans, and many detached tribes of India, Africa, and the other continents and islands. Must there not be thousands, not to say millions of people living to-day who have not the least commingling of blood in their veins for thousands of years at least?

Suppose we say that there are only twenty different people, a very conservative estimate, and take one from each as totally unrelated to the others for say one thousand years past, and reduce the number of their estimated progenitors (1 094 millions) to 10 per cent to meet Mr Eckles's blood relationship (a very generous allowance, as the isolation of groups works both ways, and tends to keep distant communities apart), and we arrive at 2,000 millions living at that date against the 1 500 millions of to-day

WHAT IS HEAT LIGHTNING?

To the Editor of the SCIENTIFIC AMERICAN

I note in your issue of August 28th a communication from Mr A Graham of Topeka, Kan, regarding the classification of lightning I had the opportunity several years ago of proving that the so-called "sheet" or "heat" lightning is nothing more or less than a reflection, as he states of the regular "chain" lightning

I had a discussion with the man in the telegraph office in a small town on a railroad running directly east and west regarding what he called "heat" lightning I maintained that it was lightning flashes so far away or so high in the clouds, that we could neither see the flash itself nor hear the thunder

During the whole summer we watched the storms very closely, practically all of them came from the west, so we were able, by calling up the operators in the different stations, to tell just what was actually occurring, and in every single instance we could find other operators near us reporting "sheet" lightning while those at twenty five, thirty, forty, and even fifty miles off were reporting regular lightning, accompanied with thunder

It is the writer's opinion, based upon the observation of that summer that there is but one kind of lightning, viz., that which we see reaching from cloud to cloud or from cloud to earth when the storm is near by The same kind, in fact, that we can ourselves produce on a miniature scale between points of a spark plug in an automobile engine cylinder The appearance of so-called "heat" lightning is very easily produced on a cloudy or foggy night, by the jumping of a trolley wheel from its wire, thus making an arc that throws its reflection on the clouds.

HOW FINGER AND THUMB MARKS WERE DISCOVERED THROUGH A PHOTOGRAPHIC PROOF.

To the Editor of the SCIENTIFIC AMERICAN

A few weeks ago a photographic proof upon a piece of gelatine printing-out paper was given to the writer to tone with other photographic prints, in the usual chloride of gold and borax toning baths No particular attention was paid to this print It was treated the same as the others, namely, washed well, toned, fixed, and washed well again for half an hour

The prints were all squeeged upon thoroughly-cleaned ferrotype plates. When the prints were dry they were lifted in the usual way, by inserting the tip of a jack-knife blade at one corner, and pulled off. Every print came off perfectly clean, leaving no impression upon the ferrotype plate, except the proof that had been toned Upon examining the part where this proof had been dried, it was discovered that quite a number of mixed finger marks were clearly discernible upon the ferrotype plate, although not visible in the print. The explanation appears to be this Gelatine being a colloid body, the greasy matter, lactic acid, and sodium chloride contained in the perspiration of the skin became impressed and retained upon the gelatine surface, although not sufficiently to become visible to the human eye. Traces of lactate and chloride of silver being formed, became partly washed out previous to toning, and completely dissolved upon fixing, but the greasy matter remained. This too would become more perfectly retained when the gelatine came in contact with water, the result being that the greasy matter, not being affected by any of the chemicals used in toning and fixing, became manifest when the print dried down upon the ferrotype plate, leaving this greasy matter upon the japan, thus giving an admirable clue in the line of detection

ELECTRICAL FIREBALLS WHAT ARE THEY?

To the Editor of the SCIENTIFIC AMERICAN

This question, that I sent to the English Mechanic and which was published in that journal on July 30th page 618, letter 576, brought out a number of very interesting answers in subsequent numbers of the same paper, notably in those of August 13th and August 20th, and if your correspondent, Mr A. A Graham, who writes the article on Lightning' in the SCIENTIFIC AMERICAN for August 28th, will take the trouble to read the letters mentioned, in the English Mechanic, he may have occasion to modify his opinion regarding 'electrical fireballs."

Mr Graham says "The recorded instances of fireballs are so rare and questionable, with no evidence of their electrical nature, that the information is not sufficient to enable one to form even a belief in their occurrence '

While entertaining very much the same belief as Mr Graham I received a letter from a very intelligent lady, who is spending the summer in a bungalow situated in the pine woods bordering on Buzzard's Bay, Massachusetts

She writes as follows "I was awakened about 2 o clock by hearing rain and rose to close the windows The darkness was appalling There was a flash of lightning and a loud peal of thunder, and as I got to the window I saw a luminous ball descending some distance away and when I looked again some minutes after there were numerous luminous bodies along the roof of a house about fifty feet away but these lights were stationary and I watched them till the first streaks of day"

Of course, we know very well what the immovable lights were The St Elmo fire an electrical appearance, is quite commonly seen on the masts and spars of vessels, and on projecting points of high buildings, but the fireball is a very different affair, and there seems to be abundant evidence of its occurrence that is if such scientific men as Arago Humboldt Flammarion and E B Dunn of the U S Weather Bureau may be considered good authority, and in addition to these, letter 69 in the English Mechanic of August 20th from Edwin Holmes, a member of the Royal Astronomical Society who describes a fireball that he witnessed himself may serve to satisfy Mr Graham that such things as fireballs are not entirely deceptive appearances and I would be very glad myself to hear from readers of the SCIENTIFIC AMERICAN what they know about them J D HYATT

DOES MUNICIPAL OWNERSHIP PAY?

To the Editor of the SCIENTIFIC AMERICAN

In your issue of August 21st second column on page 123, you speak of the effect that the electrifying of the London tramways has had on the passenger receipts of the Great Eastern Railway of England You make the following statement

"The Council Tramways are a municipal undertaking, and while giving good service have been run hitherto at a loss, the deficit being paid out of the rates."

As a matter of fact the report presented a few months ago by the London County Council on the results of the year 1907-8 showed that the gross receipts were £1,663,000 ($8 315 000), which was a surplus on working of £493,000 ($2 465 000) and a net surplus after payment of interest on capital outlay and providing for the repayment of debt of £45 406 ($227,030) The latter amount was carried to the renewals fund

There has been such a persistent attempt to deprecate municipal ownership throughout the United States, that it is hard to find justice given the subject. This attempt to mold public opinion through the press has been largely brought about by a "press bureau," maintained for that special purpose While I am personally of the opinion that municipal ownership in the United States would result in failure (because of the deplorable amount of graft and corruption in the administration of municipal affairs) yet it does seem as though municipal ownership *per se* should be given fair show ARTHUR J CRAMP

Chicago, Ill

EDITORIAL ADDENDUM TO LETTER.

We appreciate the tone as well as the substance of this correction, and regret that we had not noticed the later report quoted The note was based on a general impression, which was however correct as to the deficits in administration of the L C C. tramways in former years. While we are desirous of treating the question of municipal ownership as impartially as possible however we would point out that even in the report mentioned the net surplus was carried over to renewals fund with the probability that it would be more than used up in the ensuing year The only justification of municipal trading, in our opinion is that it should be carried on at a profit the *profit going to the relief of the rates* Since the above-mentioned surplus was not so used it can hardly be considered as a profit besides which it does not represent interest upon the capital expenditure of the Council at a rate upon which any private corporation could survive

◆

SUPERSENSITIVENESS OF THE BLIND

To the Editor of the SCIENTIFIC AMERICAN

In a recent issue of the SCIENTIFIC AMERICAN I noticed an article on the supersensitiveness of the blind in which cases were cited of remarkable acuteness of the remaining four senses The article in question calls to mind a notable experience I had in New York city in 1896

It will be recalled by thousands of people that the late Charles Broadway Rouss the blind merchant of that city offered one million dollars to anyone who would restore his sight The offer was sensational and was widely circulated in every civilized nation Thousands of letters, written in many languages, poured into the big Broadway store suggesting remedies, and the blind merchant was besieged by many offering treatments for the restoration of his sight Rouss although blind was a busy man always at his desk directing the affairs of his great establishment He was too busy to take treatments he declared and so he selected a substitute whose name was Martin and who was alike blind from atrophy of the optic nerve He was too poor to pay for treatments and was glad to act as a substitute for the millionaire who agreed to defray his expenses It was understood that Rouss would undergo any treatment that would benefit Martin

I made arrangements with Rouss for the treatment of Martin and accordingly Martin came to my residence every day for about two months The treatment was electrical from a primary battery of my own invention The files of the New York World of July 31st and Journal (since changed to American) of August 1st 1896 will show that my treatment of the case became quite sensational I believed that Martin had made some slight improvement and might regain his sight I finally gave up the case however deciding with all oculists that atrophy of the optic nerve is incurable

Martin was a native of New York city and had been blind nine years He was of a fearless and impetuous disposition and went about over the city without a guide He passed up down and across the great thoroughfares frequently and only a few times collided with a bicycle which vehicle he detested I was with him on occasions when I marveled at the perfect freedom with which he walked along the crowded streets showing not the slightest timidity and requiring no aid whatever from me

Once I left my residence on 22nd Street near Eighth Avenue with Martin for a walk through the city to Third Avenue and thence down town In passing he would name with great accuracy the streets and notable buildings His eyes showed no indication of blindness and no one suspected that he was blind I was amazed to see him cross Broadway at 14th Street with perfect ease and imagine my astonishment when he shied around some timbers that had been set up across a sidewalk to prop the wall of a building under going repairs. He got off and on street cars without a blunder and made his way across crowded streets without betraying his blindness. He used no cane nor did he feel his way with his hands Had I not known that he was actually blind I would have believed he was feigning.

I asked him how he knew his way and avoided collisions and he invariably told me he did not know He only knew that he cared nothing for his life and often remarked that he would rather be dead than blind He seemed to be guided by what I shall term a miraculous instinct superinduced by a subconscious mental condition I am inclined to the belief in the absence of a better theory that he was directed by what Hudson terms 'the subjective mind '

Owing to the careful adjustment and regulation of temperature necessary in bacteriological incubators a new incubator has recently been built which will be heated by electricity and which it is expected will thus overcome the difficulties with gas-heated incubators Incandescent lamps are used in the new heater to maintain the required temperature A new mercury regulator controls the lamps. The instrument was tested quite recently for a run of forty five days, and the variations in temperature during this time were practically nothing The incubator is formed with a triple wall providing a water jacket and an air space and is covered with asbestos finished in white enamel

DEVELOPMENT OF THE HUDSON RIVER STEAMBOAT.

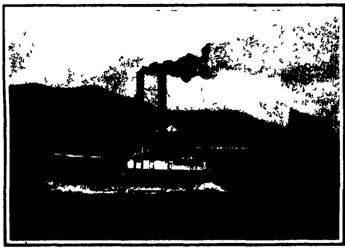
In that broad field of human activity which is covered by the term "engineering" there is probably no product of American design and construction that bears more distinctive national characteristics than the American river steamboat. Also we venture the assertion that there is no type of passenger vessel plying upon river, lake or ocean that presents such a perfect picture of graceful lines and contour or carries such a suggestion of speed as the American river steamboat. That it should show such undisputed beauty is surprising when we bear in mind that this type of boat has been developed during the past hundred years along lines of the strictest utility and under the stress of the most severe competition, a competition whose intensity has not been exceeded even in the construction of the competing railroads which have thrown their elaborate network over the face of the country. Every one of the peculiar characteristics of the river steamboats has been due not to the mere caprice of the builder but rather to certain exacting physical conditions of the work which had to be done. The shoal draft, the wide overhanging guards, and even that distinctively American survival (we had almost said anachronism) the walking beam engine, are instances of "the survival of the fittest" after one hundred years of endeavor to find the best type of boat for this work.

The successful trip of the "Clermont" to Albany in 1807, in the then incredibly brief time of 32 hours brought the new system of transportation into immediate favor and the growth of traffic, in spite of the fare of $7 for the single trip was such as to warrant the construction of four additional steamboats to meet the growing demand. The "Car of Neptune" was built in 1808, the "Paragon" in 1811, the "Firefly" in 1812, and the "Richmond" in 1813-1814. It was not to be expected that so profitable a venture would be allowed to pass unchallenged, and a company was formed at Albany which built two boats to run in opposition to the Fulton line. Fulton and Livingston, however, were granted a perpetual injunction against the opposition company and the two vessels were turned over to Fulton and broken up. Rendered thus doubly secure in the possession of their exclusive rights in the State of New York, Fulton and Livingston took out additional patents and settled down to the development of the river carrying trade. Not much is known of the four successors to the "Clermont" mentioned above beyond the fact that the weakness of construction which was evident in the "Clermont" was remedied. The rectangular cross section was abandoned, a keel and keelsons were introduced to give the longitudinal stiffness, the flat bottom was abandoned in favor of a dead rise, and the bilge was given the rounded form which characterizes the later vessels.

In 1811 Aaron Ogden, Governor of New Jersey, petitioned the New York Legislature against the Fulton monopoly, but was unsuccessful. He built a steamboat called the "Sea Horse," to run between Elizabethtown, N. J., and New York city, and this vessel is credited by John H. Morrison in his "History of Steam Navigation" with being fitted with an engine that was the pioneer of the American beam engine. Subsequently Livingston and Fulton gave Ogden permission to run his steamboat on his ferry route for a period of ten years. Out of this arrangement came the litigation ultimately carried to the United States Supreme Court, by which the steamboat monopoly, which had existed for seventeen years, was broken. One of the most active opponents of the Fulton Livingston interests was "Commodore" Vanderbilt, who in the early 20's was operating two boats, the "Bellona" and "Stoudinger," from the Battery across the Bay to Elizabethtown, N. J. Robert R. Livingston, Fulton's backer and close associate, died in 1814, and Fulton on February 24th, 1815.

There can be no doubt that the monopoly granted to Fulton served to delay the development both of the steamboat and of river transportation in general. The decision of the Supreme Court in 1824 opened the river to steam navigation by boats propelled "by fire or steam," and forthwith the improvement of the steamboat began to go forward by leaps and bounds. The original North River Company was at once confronted by opposition lines. The Hudson River Line built three boats, the "Constitution," "Constellation," and "Independence," and certain people in Albany set afloat the "De Witt Clinton." The year 1824 is notable for the launching of the first steamboat to carry compound engines, the "Henry Eckford." The cylinders were 12 and 24 inches in diameter and the stroke 4 feet. The new type of engine gave satisfaction, and it was used in several vessels, including the "Commerce," launched in 1825, of which we present an illustration, and the "Sun," of about the same date. The dimensions of the "Commerce" show the trend of development. She was of less length than the "Clermont," 130 feet as against 150 feet, but of nearly twice the beam, the "Clermont" having been altogether too narrow for stability. Her engines had cylinders 16 and 30 inches in diameter by 4 feet stroke. Altered in 1852 and renamed "Ontario," this remarkable vessel was not finally broken up until the year 1894. The "Sun," whose engines were of the same compound model and of the same dimensions, is credited with having made the trip from New York to Albany in the year 1826 in twelve hours and sixteen minutes, with thirteen landings, so that in the intervening nineteen years since the voyage of the "Clermont," the time of passage had been reduced about two-thirds.

The year 1826 is notable for the fact that John Ste-

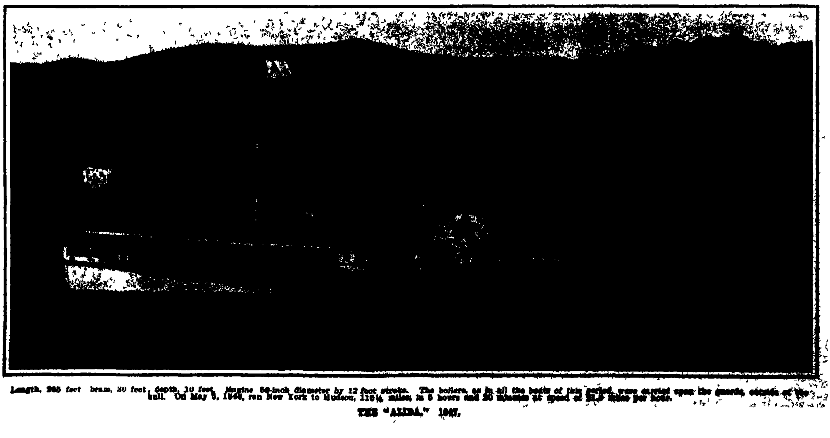


Length 130 feet beam 24 feet, depth 8½ feet Engines Cylinders 16 inch and 30 inch diameter by 4 foot stroke Altered in 1852 and renamed "Ontario." Broken up in 1894

THE "COMMERCE" 1825

Length 180 feet beam, 28 feet depth 9 feet Driven by two engines. Cylinders, 42 inch diameter by 10-foot stroke Carried two boilers on each guard In August, 1832 ran from New York to Albany in 9 hours and 40 minutes.

THE "CHAMPLAIN" 1832



Length, 265 feet beam, 30 feet, depth, 10 feet. Engine 56-inch diameter by 12 foot stroke. The boilers, as in all the boats of this period, were carried upon the guards, outside of the hull. On May 5, 1848, ran New York to Hudson, 115¼ miles, in 5 hours and [illegible] minutes at speed of [illegible] miles per hour.

THE "ALIDA," 1847.

yers, the Fulton monopoly having been broken, entered the Hudson River passenger business, and applied his genius to the design of engines and steamboats; and it is doubtful if anyone who worked at the problem in the first half century succeeding Fulton has left a deeper impress. Possessed of a natural gift for engineering and being a man of wealth and the owner of works of his own, he approached all problems from the scientific standpoint, carrying on careful experimental work before he started the construction of the full-sized engine or boat. To him we owe the present open-skeleton walking beam, with its inclosing wrought-iron strap. In his new "Philadelphia," 1826, he introduced the practice of carrying the boilers outside the boat upon the guards, and in her engine he introduced balanced poppet valves and wrought-iron side pipes. In the following year he introduced (in the "North America") for the first time the familiar truss or "hog frame" for stiffening the hull, a device which has survived in the Hudson River steamboat to the present day.

It was at about this time that the practice was followed in some of the steamboats of providing two separate engines, one for each paddle wheel. The "North America," above referred to had engines of this kind, as did the "Champlain,' 1832, which is shown in one of our illustrations. The "Champlain" also illustrates another point of current practice in the possession of four separate boilers, one carried forward and one aft of the wheel house on the guards on each side of the vessel. The 'four-pipe boats with their two oscillating walking beams must have presented an odd appearance to the people of that day, who were accustomed to the one- and the two-pipe practice of the previous years. The next vessel to make a considerable cut in the running time to Albany after the performance of the 'Sun" was the Novelty" which on May 31st, 1832, ran from Albany to New York in nine hours and forty-seven minutes. On August 23rd of the same year, the "Champlain' made the run north in nine hours and forty nine minutes.

The period from 1830 to 1840 was marked by a truly wonderful development in the speed of the Hudson River steamboat. At that time there were no steam vessels anywhere in the world that could approach these famous craft in speed and that American shipbuilders and engineers should have gained such a commanding lead over the Old World is to be attributed to the facilities afforded by our magnificent rivers, to the keen competition between the various companies and to the fact that then as now it is the fastest means of conveyance that wins the popular favor. Two of the swiftest boats of the day were the 'Swallow" which was built for the original North River line and the Rochester built in the same year, 1836, for the People's Line which was started in 1835. The "Swallow after frequent alterations to engines and hull with a view to increase of speed was finally equipped with a cylinder of the huge diameter for those days of 52 inches and the Rochester with one of 50 inches diameter. The particulars of these boats as given by Morrison show to what an advanced stage

(Continued on page 227)

As originally built in 1861: Length was 280 feet; beam, 34½ feet, depth, 10½ feet. Engine Cylinder, 62 inch diameter by 12-foot stroke. Vessel rebuilt in 1875 and 1881. On August 7th, 1874, ran from New York to Poughkeepsie 74¾ miles, in 3 hours and 19 minutes at speed of 22.54 miles per hour.

THE "MARY POWELL." 1861

As originally built in 1880. Length, 285 feet. beam, 40 feet, depth, 11½ feet. Cylinder 75-inch diameter stroke, 12 feet. Subsequently lengthened to 325 feet. Has feathering paddle wheels. On October 22d, 1880, ran from 22d Street New York to Poughkeepsie 72¼ miles in 3 hours 8 minutes at speed of 23.28 miles per hour. The Albany and the New York' were the first large Hudson River boats to be built of iron.

THE "ALBANY" 1880

Length, 412 feet, beam, 50 feet, draft, 8 feet. Beam engine, cylinder, 81 inch diameter, 12 foot stroke. Horse-power 3,800. Speed maximum 20½ miles per hour. Contains 350 state rooms. The dining-room can seat 800 guests. There are four decks for the accommodation of passengers.

THE "ADIRONDACK" FOR NIGHT SERVICE. 1896

Length, [illegible] feet; beam, 48 feet; width over guards, 82 feet, draft, 7½ feet. Inclined engine, one 45-inch high pressure, two 70-inch low pressure cylinders, with 7-foot stroke. Steam, 170 pounds. Speed on trial trip, 24.5 miles per hour. Has six decks, four of which comfortably accommodate 5,000 passengers.

THE "HENDRICK HUDSON," 1906. DAY SERVICE.

Length 348 feet, beam 42 feet, draft 7½ feet. Beam engine cylinder 75-inch diameter by 12-foot stroke. Has feathering paddle wheels. This vessel has the finest underwater body of all the Hudson River boats. Her maximum speed is 23½ knots.

THE "ROBERT FULTON" 1909 DAY SERVICE.

AMERICAN STEAMBOATS PRIOR TO THE "CLERMONT."

It is one of the estimable qualities of Robert Fulton that in spite of the obvious temptation so to do, consequent upon his brilliant success with the Clermont he never claimed the distinction of being the original inventor of the steamboat He was perfectly familiar with the ingenious work in the development of steam navigation which had been done both in the United States and in Europe during the two decades preceding the successful trip of the Clermont He had intimate knowledge of the previous history of the art, he was personally acquainted with the more successful inventors, and as a guest had made trips on at least one of the more successful boats The present celebration so far as Fulton is concerned is held in honor of the *successful inauguration of practical commercial steamboat navigation on the Hudson River* There is glory enough surely in this to make a fitting crown for the life work of one man Were Fulton in our midst to-day he would be among the first to do justice to the work of his predecessors and contemporaries in other times and on other waters

It is impossible within the limits of the present article to describe at any length the dozen or more steamboats big and little which were built and tried *with varying degrees of success in America prior to* 1807 We must content ourselves with the following summary (based on Preble's history) of these early efforts followed by a brief sketch of the remarkable work of Fitch and Stevens

The first boat successfully propelled by steam in America was one built by John Fitch which was tried on the Delaware July 27th 1786

The second American steamboat also built by Fitch was tried on the Delaware in 1787

The third boat built by James Rumsey and driven by a water jet was operated at Shepardstown on the Potomac September 3rd 1787

The fourth steamboat built by Fitch ran from Philadelphia to Burlington in 1788

The fifth steamboat also built by Fitch, made eight miles an hour over a measured course at Philadelphia in 1789, and in 1790 was placed in regular service on the Delaware as a packet, its sailing dates being advertised in the local press.

The sixth steamboat, a stern-wheeler, built by Capt. Samuel Morey of Connecticut, sailed from Hartford to New York, with Chancellor Livingston and others on board in 1794

The seventh steamboat, by Fitch, tried on the old Collect Pond now the site of the Criminal Court building and City Prison, New York, was driven by both paddle wheels and a screw propeller Chancellor Livingston was aboard on this trip and a very crude model of the boat shown in the accompanying illus*tration is now in the keeping of the New York His*torical Society

The eighth boat by Morey, was tried on the Connecticut River in 1797

The ninth steamboat was built to plans of Chancellor Livingston by a Mr Nisbet, and tried at De Koven's Bay south of Tivoli in March 1798

The tenth steamboat was a model side-wheel vessel built by Fitch and tried on the Ohio in 1798

The eleventh boat built and designed conjointly by Nicholas Roosevelt, John Stevens, and Chancellor Livingston, had side chain wheels driven by a steam engine. It was tried successfully in October, 1798, and with the Spanish Minister on board as a guest made three miles an hour

The twelfth steamboat, built by Col. John Stevens, was a 25-foot flat-bottomed boat, which was driven by a screw propeller on the Hudson River at a speed of four miles per hour in 1803 and 1804.

The thirteenth steamboat, built in 1804 by Stevens, was propelled by twin screws at a speed of seven to eight miles per hour, and made several trips on the Hudson River

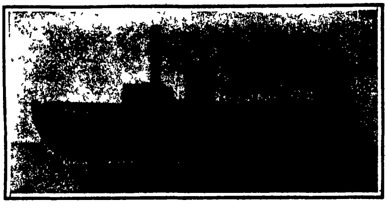
The fourteenth steamboat, built by Oliver Evans in 1804 was a large scow, or lighter, driven by a paddle wheel at the stern.

The fifteenth and last steamboat before 1807 to make a trip under her own steam was a large pirouge, with side paddle wheels, called the "Phœnix," built by Stevens in 1806-7, which, being debarred by Fulton's monopoly from navigating on the Hudson, subsequently steamed to Philadelphia by sea, and thus became the first steamship to make an ocean voyage.

It should be understood that although the above enumeration includes vessels that were actually moved by steam, no claim is made that they were all of a practical character Of the Americans who turned their attention to the development of the steamboat in the pre-'Clermont' period two men, in our opinion stand head and shoulders above their competitors, namely, John Fitch and John Stevens, the first, for *the reason that as far back as 1790* he placed on the waters of the Delaware a steamboat which ran on a regular schedule, was advertised extensively in the local papers, and carried freight and passengers at specified fares, the latter, because he was the first to apply the screw propeller as the sole means of propelling a boat, that he used tubular boilers and high-pressure steam, and that he was the first to adopt that system of twin propellers which subsequently became the standard method of propulsion throughout the world.

JOHN FITCH.

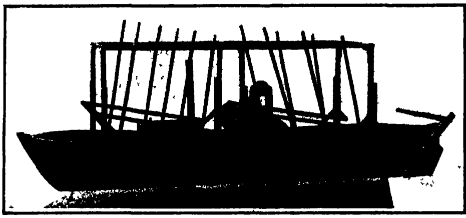
John Fitch, stands out as a splendid type of a large class of ingenious, courageous, but poor inventors, who did so much to promote the industrial development of the country during the early years of the young republic. Born at



Rumsey's boat was propelled by a steam engine and pump which drew in water through the bottom and discharged it in a jet at the stern Made four miles an hour in a short trial on the Potomac but never reached the stage of practical operation

(From photograph of the model in the Smithsonian Institution taken especially for the SCIENTIFIC AMERICAN)

JAMES RUMSEY'S STEAMBOAT OF 1787



This boat made six miles an hour on the Delaware It was propelled by vertical paddles driven in sets of three by side rods operated by a steam engine

(From photograph of the model in the Smithsonian Institution)

JOHN FITCH'S STEAMBOAT OF 1787

This crude model was made from memory in 1852 by a witness of the trials of the boat on the old Collect Pond New York city

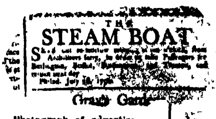
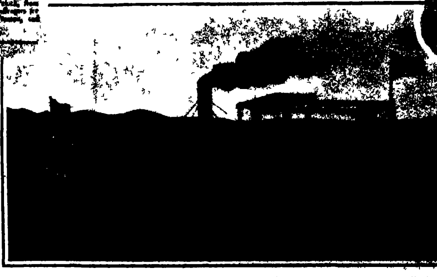
JOHN FITCH'S STEAMBOAT OF 1796



THE

STEAM BOAT

Photograph of advertisement in the "Federal Gazette" of Philadelphia July 26th, 1790

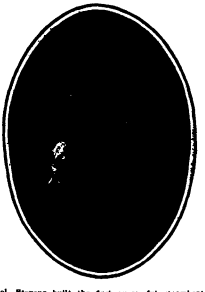


This boat, 60 feet long driven by an engine with cylinder 18-inch diameter, designed and built by Fitch, was put in regular service, advertised in the Philadelphia papers, and for three months in 1790 sailed according to schedule between Philadelphia, Trenton, and way points. Its average speed was 7 miles an hour. It was propelled by paddles at the stern.

JOHN FITCH'S STEAMBOAT, WHICH SAILED REGULARLY BETWEEN PHILADELPHIA AND TRENTON IN 1790

Photograph of advertisement in the "Pennsylvania Packet" of Philadelphia of June 14th, 1790.

Windsor, Conn., on the 21st of January, 1743, in moderate circumstances, he learned the trade of clock making, and at twenty-six years of age moved to New Jersey and then to Philadelphia, where he became a strong partisan on the American side in the dispute between the colonies and Great Britain. He was made lieutenant of a company raised at Trenton, but ultimately he found his sphere of usefulness in the gun factory at Trenton When Washington crossed the Delaware Fitch moved with the Continental troops to Pennsylvania. In 1780 he was appointed a deputy surveyor, and ultimately struck out westward for the purpose of surveying lands lying beyond the Ohio River In 1781 he started for Fort Pitt, now Pittsburg Later he was captured by the Indians, endured severe privations, and was finally carried by them to Canada, where he fell into the hands of the British After his liberation he again took up the work of surveying the unknown lands of the West, and ultimately in 1785, turned his attention to his great life-work of inventing a boat to travel by the power of steam Beyond a natural aptitude for mechanics, Fitch was entirely unfurnished for this difficult task Although steam-engine building was a recognized trade in England and had been for many years, there were at this time but three steam engines in the whole of America, and the country was absolutely without suitable means for steam engine manufacture In his quaint 500-page manuscript autobiography now in the Philadelphia Library, Fitch writes "Although it was not to my credit, I did not know that there was a steam engine on earth when I proposed to gain a force by steam" He read up all the scant literature he could obtain on the subject formulated his plans and on September 27th 1785, presented a drawing and model of his boat to the American Philosophical Society at Philadelphia The model shows the *method of propulsion* by an endless chain provided with paddle boards He endeavored to interest Franklin and Gen Washington in his plans, neither of whom however gave him much encouragement. He formed a company and on March 18th, 1786, secured from the Legislature of New Jersey the exclusive rights for steam navigation in that State It was at this time that he associated himself with Henry Voight a clock maker of unusual mechanical ingenuity and skill The task which these men had set themselves was Herculean There were no machine shops nor the necessary tools for the accurate work required, and through the subsequent years of experimentation they had to feel their way amid a thousand discouragements of poverty and ignorance, to the final success which crowned their efforts five years later They first built a model steam engine with a cylinder of one inch diameter which was too small for a demonstration Then a new model with a 3-inch cylinder engine, was erected in a small skiff, and a trial was made with Fitch's endless chain paddle-boards but without success. Then it occurred to Fitch to move the boat by oars or paddles, working on the side, and moved by cranks operated by the engine This was tried on the skiff with the 3-inch engine and on the 27th of July, 1786 the first boat propelled by steam in America made its trial trip successfully on the Delaware. Encouraged by the passage of a law by the State of Delaware in 1787, securing Fitch's right to the invention, fresh advances of money were made by the shareholders, and a boat 12 feet wide and 45 feet long was equipped with an engine having a 12-inch cylinder After much experimental work with the condensers, this boat, on August 22nd 1787, was propelled on the Delaware in the presence of practically all the members of the Convention who were then sitting in Philadelphia to frame the Federal Constitution Certificates of perfect success of this trial were given by Gov Randolph of Virginia David Rittenhouse the astronomer and other notable men An engraving and description of the boat made from the plans were published in the Columbian Magazine for December 1786 The cylinder was double-acting and condensing. Fitch introduced the jet condenser which he believed to be original with him, although it had been previously invented in Europe The boat was driven by six *pairs of oars* or paddles which were pivotally connected in sets of three to four horizontal driving bars, operated by cranks on crank disks driven by the engine. Fitch preferred these paddles to the paddle wheel, because he considered that the latter involved a great waste of power due to the obliquity of the wheels on entering and leaving the water Fitch's objection to the paddle wheels was theoretically correct, and its inefficiency was not corrected until the invention half a century later of the *feathering paddle wheel*



Col. Stevens built the first successful steamboat driven entirely by the screw propeller, the first twin propeller boat and the first steamboat to make an ocean voyage

COLONEL JOHN STEVENS, 1749 1838

The third steamboat built by Fitch was a much larger craft and was driven by a greatly improved engine The new boat was 60 feet in length and 8 feet in beam Its engine also had 12-inch cylinder but as the result of an improved condenser designed by Fitch it developed considerably more power than the engine in the preceding boat Furthermore it should be mentioned that this was the first steam boat equipped with a tubular boiler the invention of Voight The oars, or paddles *were removed from the sides* and placed at the stern Toward the close of *July 1788* she made the trip of twenty miles from Philadelphia to Burlington and on the 12th of October she made the same trip in three hours and ten minutes with thirty passengers on board The boat continued in more less experimental operation during 1788 and 1789 The story of the troubles of Fitch and Voight in the endeavor during this time to perfect their engine as contained in Fitch's autobiography is of absorbing interest No less than seven different condensers were tried and rejected Finally an 18-inch steam cylinder and a jet condenser of Fitch's design were installed and at last in the words of Fitch "On the 16th of April (1790) got our work completed and tried our Boat again and altho the wind blew very fresh at the north east we reigned Lord High Admirals of the Delaware and no boat in the River could hold its way with us, but all fell astern although several sail boats which were very light and heavy sails, that brought their gunwales well down to the water came out to try us

Shortly afterward Rittenhouse the astronomer Dr Ewing Gen Irvine and others were favored with the novel experience of a steam voyage, and now at last public journals began to give well deserved notice to the successful efforts of these indefatigable inventors The following paragraph was published in the Gazette of the United States May 15th 1790 and widely recopied throughout the Union Burlington May 11 1790 The friends of science and the liberal arts will be gratified in hearing that we were favored on Sunday last with a visit from the ingenious Mr Fitch accompanied by several gentlemen of taste and knowledge in mechanics in a steamboat constructed on an improved plan From these gentlemen we learn that they came from Philadelphia in three hours and a quarter, with a head wind the tide in their favour On their return by accurate observations they proceeded down the river at the rate of upwards of seven miles an hour' Subsequently on June 16th Gov Thomas Mifflin and nine members of the

EUROPEAN STEAMBOATS PRIOR TO THE "CLERMONT."

As in America, so in Europe, the quarter of a century preceding the successful inauguration of steamboat service on the Hudson River was a period of *extraordinary interest among inventors in the possibilities* of steamboat navigation, during which a great amount of thought and experimental work was devoted to the development of a successful steam-driven vessel In the present chapter we shall touch lightly upon those inventors who merely drew up plans took out patents, and made more or less successful models of steamboats our attention will be devoted more specifically to the clearly recorded and well-authenticated instances in which steamboats of useful size were actually propelled by steam

Following this plan, we may dismiss at once the oft-asserted claim that a vessel of some 200 tons, built by Blasco de Garray a *native of Biscay*, was propelled by steam at Barcelona in Spain in the year 1543 Careful search by investigators has revealed two letters signed by Garray and dated 1543, describing experiments with different vessels both of them moved by paddle wheels *turned by men* There is no mention of the use of steam or anything to indicate that this motive power was contemplated

The Marquis of Worcester published a book in 1663 in which mention is made of an engine and of the ability of the inventor to make the vessel which carried it go against the stream which the more rapid it is the faster it shall advance" His patent, however *contains no suggestion* that he had any idea of using steam

Although the name of no inventor in the early part of the eighteenth century is more closely associated with the design of the steamboat than that of *Jonathan Hulls there is no proof* that he ever built and operated one At the same time Hulls was a man of unusual intelligence and of considerable mechanical skill His patent taken out in 1736, describes the invention as a machine for carrying ships and vessels out of or into any harbor or river against wind and tide The following year he published a pamphlet in London describing his invention and it is curious that, like many early experimentalists, he considered that its greatest usefulness would be found in the towing of vessels The illustration of his boat, given on page 220 was drawn from his very complete description of the mechanism of the boat and Admiral Preble of the United States navy in his work 'On the Origin and Development of Steam Navigation, says that there can be no doubt of his having been the first inventor of an ingenious and practicable mechanism for propelling vessels by a condensing steam engine and by paddle wheels and this be it remembered was as far back as 1736 Writing over a quarter of a century ago again the same author says The following doggerel is still the burden of a common street ditty among the boys of Campden of Gloucestershire, Hulls's native place

Jonathan Hulls,
With his patent skulls,
Invented a machine
To go against wind and stream,
But he being an ass,
Couldn t bring it to pass,
And so he was ashamed to be seen'"

Truly a prophet is not without honor save in his own country

It is a disputed point whether to Denis Papin, the great French engineer and professor of mathematics at the University of Marburg is due the credit of being the first *to* make a steamboat run upon a public waterway Preble however is of the opinion that his correspondence with Leibnitz, which was brought to light during the latter part of the nineteenth century, fully proves that Papin actually constructed a steamboat which he ran upon the river Fulda in 1707 It is certain that he met with the seemingly inevitable ridicule and abuse Disgusted with the conduct of the Hessians he determined to go to London in his steam vessel and descended the Fulda as far as Munden where the boatmen laid violent hands upon him, and destroyed his little craft

Next to Papin comes the Marquis de Jouffroy who in 1781 built a steam vessel 150 feet in length and 15 feet in beam which according to a document now in Paris was propelled by steam for fifteen minutes against the stream

WILLIAM SYMINGTON

The credit for the invention and construction of the first steamboat to be successfully applied in Europe to useful navigation is due a Scotch engineer, William Symington, who attacked the problem on original lines, and produced a vessel the "Charlotte Dundas," which in many respects was half a century in advance of the state of the art Symington was born in Scotland in 1764 Educated for the church, his taste for mechanical philosophy, he tells us, led him to direct his studies to the exercise of the profession of a civil engineer He obtained patents for several improvements in the steam engine, and designed a steam carriage, which in 1786 he submitted to several learned and scientific men in Edinburgh. Here he met Patrick Miller of Dalswinton, a wealthy banker, who informed Symington that he had "spent much time in making experiments as to the propelling of vessels upon water by using wheels in place of sails or oars. These wheels he had put *in motion*, applying the strength of men to the turning of a handle or winch." Symington told Miller that he believed a steam engine might be constructed for the purpose, and he proposed that favorite method with early steamboat inventors, of communicating a rotary motion to the paddle by the alternate action of ratchet wheels. The first experiment was made with a two-cylinder engine, the cylinders being of 4 inches diameter and 18 inch stroke. *It* was installed on a double-keel vessel, and tried on the Dalswinton estate in 1786, with satisfactory results. The next experiment was upon a larger boat, 60 feet in length, belonging to Miller, which was already equipped with man-operated paddle wheels. *In this* vessel Symington placed a two-cylinder engine, each cylinder being of 18 inches diameter and 3 foot stroke, and in October 1789, with Miller and several prominent business men and engineers on board, the boat was driven at a rate of five miles an hour in still water The engraving on page 220 is based on the original plans of this boat, as given by Symington. At this point, Miller retired from business to devote himself to his estate at Dalswinton, but in the year 1800 Lord Dundas, one of the principal owners of the Clyde Canal requested Symington to take up his experiments with the steamboat, and spent about $35,000 in this work With sufficient capital assured to give him a free hand, Symington designed an entirely new boat and engine called the "Charlotte Dundas" An examination of the drawings of the vessel, as shown on pages 220 and 221 of this issue proves that Symington was an engineer of decidedly original genius. Even at that early day, his mechanical sense objected to the cumbersome overhead working beam and in a letter at that period he criticises the cylinder erected in a vertical position and the heavy working beam, and other *heavy and complicated* apparatus *of the old steam* engine and explains how by changing the position of the cylinder and 'by coupling to the end of the piston rod a crank and arm,' he 'reproduced a rotary motion without the intervention of a lever or beam' In other words, Symington in the engine *of* the "Charlotte Dundas originated the modern horizontal reciprocating engine which was destined to become the predominant type for steamboat locomotive and stationary engines and continued to be such throughout the middle period of the history of the steam engine The cylinder was double acting 22 inches in diameter and with a stroke of 4 feet It was direct-connected to the crankshaft of a paddle wheel at the stern of the boat The account of the experiment as given in his own narrative which has been confirmed by others, is as follows

Having previously made various experiments, in March, 1802 at Lock Twenty-two, Lord Dundas, the great patron and steamboat promoter along with Archibald Spiers Esq, of Elderslee and several gentlemen of their acquaintance being on board, the steamboat took in drag two loaded vessels the 'Active' and *Euphemia*,' of Grangemouth Gow and Elspine, masters, each upwards of *seventy tons* burden, and with great ease carried them through the long reach of the Forth and Clyde Canal at Port Dundas, a distance of nineteen and a half miles, in six hours, although the whole time it blew a very strong breeze right ahead of us, so much that no other vessel could move to windward in the canal that day but those we had in tow"

Since the object of Lord Dundas in employing Symington was to have him devise some cheaper means of towing canalboats than the existing method by horses, it would look as though the future of the steamboat was assured but, unfortunately, the *other proprietors* of the canal objected to the use of steamboats, urging that the waves set up would wash away the canal banks. Therefore, nothing further was done Subsequently Symington was introduced by Lord Dundas to the Duke of Bridgewater, who was responsible for the introduction of canals into England Symington impressed him so favorably that he gave him an order to build eight boats similar to the "Charlotte Dundas" for service on his canals, but the death of the Duke shortly afterward led to the canceling of the order

Among the many methods of applying the power of the engine to propel the boat that were tried by the *early inventors one of* the most popular was to use an endless chain of paddle boards, traveling over wheels or pulleys at each end of the boat, the paddles being submerged as they passed toward the stern, and being carried clear of the water as they returned toward the bow Of this type was Desblanc's steamboat, which was tried on the river Doubs in 1802. The arrangement of the engine and the chain of paddles is shown very clearly in the engraving on pages 220 and 221. The engine was horizontal, and the reciprocating motion of the piston was converted into rotary motion by means of a ratchet gear acting upon a spur wheel upon the main driving axle.

AMERICAN STEAMBOATS PRIOR TO THE "CLERMONT."

(Concluded from page 219)

Council, after a trip on the Delaware, were so greatly pleased as to present Fitch with a suit of colors for his boat.

The new venture was now ready for commercial exploitation. A schedule of sailing dates and fares was drawn up, and during the following three months there appeared in the local papers twenty-three advertisements announcing the times *of* sailing. The routes covered were to Trenton, thirty miles, to Burlington, twenty, to Chester, fifteen, and to Wilmington, thirty miles During these three months "The Steamboat," as she was popularly called, ran in regular passenger service for a total distance of between 2,000 and 3,000 miles. Limitations of space prevent any further quotation of the certificates and eulogies given by prominent men of the day We present engravings of two of the advertisements of 1790, photographed for the SCIENTIFIC AMERICAN *from* the files of the Pennsylvania Packet and the Federal Gazette, by the courtesy of Mr Abbott, the curator of the Philadelphia Library,

In view of this crowning success to the labors of Fitch and his associates, the story of the rest of his life is truly tragical. His attempt to build another and larger vessel failed for want of financial support. Had some influential, wealthy, and far-sighted patron come to Fitch's assistance at this time, there can be little doubt that the advent of successful commercial steamboat navigation would have been hastened by twenty years. But it was not to be Discouraged and embittered by failure to secure recognition and support, Fitch after an abortive trip to France, wrote an account of his life and experimental work, which he delivered to the librarian of the Philadelphia Library with instructions that it be not opened for thirty years, and then, retiring to Bardstown, Ky, he ended his unfortunate life by committing suicide.

JOHN STEVENS.

The claim of Col John Stevens to a foremost position among those who contributed to the early development of the steamboat is based upon his recognition of the value of the screw propeller, of the multitubular boiler, and of high pressure steam Like Fitch, Stevens was possessed of great mechanical ability, and to this was added the advantage of wealth and education. His claim to have built the first steam screw propeller boat to navigate the waters of any country we consider to be indisputable.

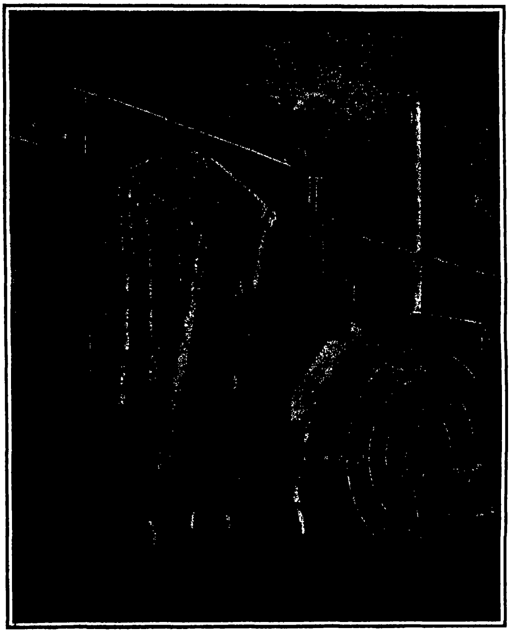
After some preliminary experiments, as recorded earlier in the present chapter, Mr Stevens designed an entirely new engine and boiler, differing from anything that had yet been attempted either here or in Europe and erected it in a 28 foot boat, which made many successful trips at speeds of between seven to eight miles an hour on the Hudson River The twin screws, engine, and the boiler are still in existence and are now at the Smithsonian Institution, Washington The accompanying illustrations are reproductions *from* photographs of this exhibit made especially for the SCIENTIFIC AMERICAN by the courtesy of the curator The cylinder was of 4½ inches diameter and 9 inches stroke Motion was transmitted from the overhead *crosshead by two* connecting rods *to* a pair *of* cranks, one on each propeller shaft. The cranks turned in opposite directions (to overcome the tendency of a single propeller to rotate the boat) and the cranks were maintained in their proper rotating position relatively to each other by means of two gear wheels on the propeller shafts. The reaction of the connecting rods against each other served the purpose of a parallel motion and maintained the piston rod in alignment. The valves consisted of two-way cocks, and they were driven by a crank on one of the propeller shafts, through the intermediary of a vertical rack and gear wheels on the spindles of the two-way cocks. The boiler is *one form of* the multitubular type invented by Col. Stevens. It has 28 copper tubes, 14 projecting from each side of a center rectangular chest.

Contemporary testimony to the successful operation *of* this boat is given in Stewart's "Anecdotes *of* the Steam Engine," published in 1829, and in an article, by Dr James Renwick contributed to Tredgold's "Treatise on the Steam Engine," published in London in 1838.

That John Stevens and his son, Robert L. Stevens, are to be credited with having built the first ocean-going steamship is proved by the well-authenticated voyage made by the "Phœnix" from New York to Philadelphia. The engines of the "Phœnix" were designed and built by Stevens. The accompanying illustration of this historic vessel is from a photograph of an old painting at the family home, Castle Point, Hoboken, N. J. Alluding to the above voyage, the late Mr. J Scott Russell, the builder of the "Great Eastern," said that Mr. Robert L. Stevens was "undoubtedly the pioneer of steam navigation in the open sea."

THE AMERICAN WALKING-BEAM ENGINE.

Looked at from the standpoint of the mechanical engineer, the most extraordinary fact in the story of the development of the Hudson River steamboat is the vitality of that early form of steam engine known as the walking-beam type. Although to-day its term of useful life lacks but a year or two of a century and it is, therefore, actually as old as the Hudson River steamboat itself, and though it represents one of the earliest and crudest methods of changing the reciprocating movement of the piston into the rotary movement of the power shaft,-the walking beam engine is to-day the prevailing type of drive on the Hudson River Most significant fact of all, when it came to the question of what type of engine to use on the 'Robert Fulton," the latest of the Hudson River fliers, built this year, it was decided that, all things considered, the most suitable engine would be one of the kind which was first placed in a Hudson River boat in the year 1811.



Cylinder, 81 inch diameter by 12 foot stroke Horse-power 3 800 Boiler pressure 55 pounds The two vertical pipes in front of the cylinder are the "side pipes," one the steam pipe the other the exhaust They communicate with transverse steam chests at top and bottom in which are the poppet valves. The latter are operated by two vertical rods which are lifted by cams on rock shafts, driven by the eccentrics.

ENGINE OF THE "ADIRONDACK."

In steam engine practice, one hundred years ago, the rocking or walking beam was the favorite method of connection between the piston rod and connecting rod We are all familiar with the engravings of early stationary engines, particularly those used for pumping in city waterworks, in which a vertical steam cylinder transmitted its power to a cast-iron overhead rocking beam, which was carried upon cast iron girders supported on cast iron pillars of elaborate classic design By the middle of the nineteenth century, this type was being discarded for the simpler horizontal engine, and to-day the few remaining walking-beam stationary engines are regarded with a strictly antiquarian interest.

In the development of the Hudson River steamboat, on the contrary the beam engine proved to be so ideally adapted to the work, that it has held its place against the multi cylinder high pressure, fast running engine, with conspicuous success In the first place, it was an easy engine to build, and, when once the foundries, machine shops, and forges had been built and a force of capable mechanics had become available, its first cost was low The engine consisted essentially of a single cylinder a walking beam a connecting rod, the A frame, which carried the main bearings of the walking beam, a jet condenser, a hot well whose piston was operated by connecting rods from the walking beam, and feed pumps operated from the same connecting rods as the hot well Judging from early prints and descriptions, the engine was quickly developed to the identical form which it carries at the present time, the principal change being the substitution, in the past quarter of a century, of surface condensers for the early jet condenser

The "Clermont," as we have shown elsewhere, transmitted the power from the cylinder to the crankshaft through a bell-crank lever Subsequently, during the succeeding two decades, use was made of a steeple engine, in which a pair of rocking beams, carried low down in the boat, were used, or the crankshaft was placed immediately below the cylinder, with connecting rods coupled from the piston crosshead to the cranks. This type, however, soon gave way to the present form with an overhead walking beam mounted on a stout timber A-frame, whose footings were bolted to the keelsons of the floor of the boat. The A frame was built of massive timbers very strongly braced and bolted, and carried at its apex the main bearings of the walking beam The guides for the crossheads were held in line by rods extending from the guides to the A-frame.

The boiler of the "Clermont" was made of copper and carried the low pressure of four or five pounds to the square inch Copper was used because iron plates were not available, but eventually, when reliable boiler plate became available iron boilers were introduced, and immediately higher steam pressures began to be used Tubular boilers were introduced in 1830 on the "Novelty," and about the year 1840 wood gave place to anthracite coal. Concurrently with the increase in boiler pressures a great advance was made in the size and power of the engines The single cylinder of the "Clermont was 24 inches diameter by 4 feet stroke The "Chancellor Livingston" of 1816 had engines 44 inches in diameter by 5 feet stroke The "Constellation ' 1825 used a cylinder 44 inches in diameter by 10 feet stroke and these remained about the maximum dimensions until the appearance of the "South America," 1840 with cylinders 54 inches in diameter by 11 feet stroke The keen contest for speed resulted in the construction of engines that were prodigious for those days and have barely been exceeded at the present time Thus in 1845 there was built for the 'Hendrick Hudson ' which was a fine vessel 320 feet long an engine with a 72 inch cylinder and 11 feet stroke, and two years later T F Secor & Co built for the 'New World" one of the fliers of that day, an engine with a 76-inch cylinder and the enormous stroke of 15 feet. Thereafter the stroke was reduced to 12 feet which was never again exceeded The largest engine afloat on the Hudson is that of the "C W Morse" of 4 000 horse-power, built in 1904 by the W & A Fletcher Company whose cylinder is 82 inches in diameter by 12 feet stroke

The permanence of the walking beam engine as the favorite drive for Hudson River steamboats, and its undoubted popularity among the directors of the companies and in the pilot house and the engine room, is largely due to the especial conditions under which the Hudson River service is operated In the first place, the upper reaches of the Hudson are very shallow during several months of the summer, and it is desirable to keep the draft of the boats as small as possible, conditions to which the broad and shallow but sweetly modeled river boats lend themselves admirably The largest vessels for the night service are of over 4 000 tons displacement, and are driven by engines of 4 000 horse-power, yet they draw only about 8 feet of water It would be a difficult proposition to drive such vessels with screw propellers. Furthermore, the large number of landings which must be made call for a boat with good manoeuvering qualities able to stop and start quickly and make quick landings at the piers. The paddle-wheel beam-engine boat has proved to be ideal for this purpose While it is well understood by the engine builders and shipping men of the Hudson River that high boiler pressures, multi-cylinder expansion, and rapidly running engines are conducive to fuel economy, it is also realized that these economies can be secured only when the engines are continuously in service Otherwise, the heavy extra capital cost of the more expensive installation is liable to exceed the saving due to coal economy The Hudson River boats are out of service for about five months of the year, and although a multi cylinder engine will run under a consumption of from 1 5 to 1 75 pounds of coal per horse-power per hour as against 2 3 pounds for a low pressure single-cylinder beam engine, the greater first cost of the plant will go far to offset the saving in the coal bill The cost of upkeep moreover of the beam engine is relatively far less The boilers built for 50 to 55 pounds pressure generally carry from 30 to 35 pounds under an easy fire. This means a lessening of boiler repairs since it is easier on steam pipes, joints and packings Moreover the engine-room force is reduced to a minimum, an engineer and an oiler generally being sufficient to take care of the average Hudson River engine

The accompanying illustrations of the 3 800-horse-power engines of the 'Adirondack" of the night line the last of the large river steamers to be built of wood will serve admirably as a reference in connection with the foregoing description of the typical river-boat engine The "Adirondack" which is 412 feet long 50 feet beam and 90 feet over the guards with four decks above the waterline, and over 400 separate berths for the passengers and crew was built in 1896 The vessel serves to show the point of size to which these stately river boats have been developed In the engraving the side of the hull and superstructure has been broken away to show the full height of the engine which was built by the W & A Fletcher Company The engine foundation consists of heavy steel keelsons The A-shaped gallows frames are built up of steel plates the legs which are of box section being strongly braced together with struts, which are also of plate steel and box section The walking beam consists of a strongly ribbed cast iron web belted with a heavy wrought iron strap the whole being firmly strapped and keyed together The cylinder is 81 inches in diameter by 12 feet stroke The two large vertical pipes seen in front of the cylinder are known as the side pipes, the one on the star

(Continued on page 229)

THREE HUNDRED YEARS OF NEW YORK.

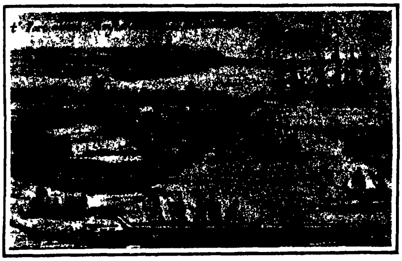
When Henry Hudson approached the opening of the upper bay he did not at first know that he was nearing the river which was afterward to bear his name He believed that it was an arm of the sea in fact that it was the northwest passage to India, that *Ignis Fatuus of so many* of the old navigators He lay in the lower bay for more than a week before he anchored in New York Harbor proper He found the neighborhood well peopled by Indians who lived in villages of fairly regular construction They were mild and inoffensive as savages go and they were quite willing to trade their tobacco and pelts for the beads and knives of the white men

Hudson at last discovered that he was at the estuary of a great river up which he sailed consuming three weeks until he reached the head of navigation at Albany Early in October Hudson turned the prow of the Half Moon homeward bringing the news of a discovery which was of the greatest possible interest among the Dutch merchants. A number of trading and exploring expeditions started out and made the trip with considerable profit to themselves

It was at last decided to establish permanent posts at the head of the river and at New York The main fort was built near the mouth of the Mohawk River and a few trading huts were built at the south end of Manhattan Island and it is from this small beginning that we are enabled to trace the industrial beginning of the city of New York

A monopoly of the fur trade was given to the New Netherlands Company which erected a trading post at New York The monopoly which was a valuable one was extended from year to year until 1621 when the Great West India Company was chartered It was under its auspices that the first real and permanent settlement in New York was made

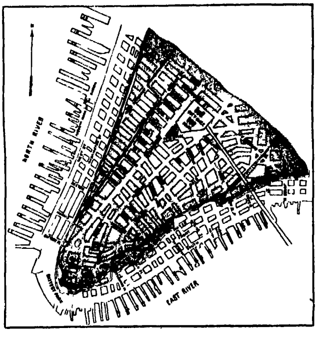
The city of New York has been very fortunate in the preservation of the early records of its settlement The early history of Rome London and even Paris is lost in obscurity while other cities such as Berlin and St Petersburg have no history of any importance and still look painfully new and as though they were planned with the aid of the T-square and drawing pen From these records we learn that the original block house with its palisades gave way to Fort Amsterdam, around which clustered the small cabins of the first settlers Some idea of the early appearance of the settlement is obtained from a view in Hartgers "Beschrijvinghe van Virginia," a copy of which we present herewith. This is the earliest known view of New York, and the little book in which it was published is of the greatest rarity To obtain a correct idea of the topography it is necessary to view the plan in a mirror, as it is reversed It was probably obtained with the aid of a camera obscura from some point on the Long Island shore and was never restored to its proper position. Although the print is on a small scale it gives considerable detail, the number of buildings shown being about thirty or thirty five. In the fort were situated the Governor's house, the chapel barracks for the soldiers, magazines and other necessary buildings



EARLIEST KNOWN PRINT OF NEW YORK CITY ENTITLED: "FORT NIEUW AMSTERDAM OP DE MANHATANS," PUBLISHED IN 1651 — POPULATION ABOUT 800

NEW YORK IN 1673

Buildings have been erected within the fortified enclosure; streets have been laid out leading to wharves. The population in 1664 had grown to 1,500 and in 1698 it was 4,937



MAP SHOWING INCREASE OF CITY AREA ALONG THE WATER FRONT OF LOWER NEW YORK. THE ORIGINAL CITY IS SHADED

There does not appear to have been any attempt to found a substantial colony until 1621, when the Dutch West India Company came into existence. It was admirably organized and they established a strongly garrisoned colony which was the nucleus of a colonial government which was in control of a vast territory which stretched from Virginia to New England. The municipality itself, however, was of almost microscopic proportions, for in 1628 we find that the inhabitants numbered only 270, but the fort was constantly increased in strength until it became a fortress of no mean magnitude for the size of the place. In 1626, Peter Minuit purchased the whole of Manhattan Island for trinkets, the aggregate value of which was $24 It would perhaps be interesting to figure up how much the interest at 6 per cent compounded at regular intervals, would be on the $24 for the period since the purchase.

In 1653, when a foray of New Englanders was expected a stockade or palisade was erected across the island from east to west, thus fortifying the outskirts of the inclosure. This was at the point where we now have a teeming center of finance — Wall Street. Strange to say, this wall prevented the natural expansion of the city for over half a century and always tended to create that congestion which still remains so overwhelmingly strong Every old and important city in Europe has been cramped within a stone girdle of fortifications and long after the necessity for this has vanished the habit of congestion remains.

The present crowded tangle of streets at the southern termination of Manhattan Island is entirely attributable to the customs of the Dutch dwellers There was little attempt made to lay out broad or convenient streets. The foot paths and lanes became the future streets, and no better example can be adduced than this, that the early pre-arrangement of the south never obtained in northern lands. One of the earliest streets was nearly parallel with the present Pearl Street and the other with Broadway, while "Dock" Street led to the shipping quays.

After a long and rather interesting occupancy by the Dutch, the flag of Great Britain was raised on September 8, 1664, and Fort Amsterdam forthwith became Fort James. There was little or no dislike of the conquerors, who made a peaceful invasion without striking a blow England's policy was not so liberal in those days as in her present handling of colonial matters. Still, however, the Dutch hardly knew that the form of government was being changed, so that now the isolated trading post became a national colonial dependency Under the old *régime* there was no home pride among the commercial owners, but the new conditions put a different aspect on the [illegible]

NEW YORK UNDER BRITISH DOMINION JUST BEFORE THE REVOLUTION

Among the landmarks are Trinity Church, the old Dutch Church, and Fort George. The population in [illegible] the inhabitants began to grow fond of their new surroundings and government.

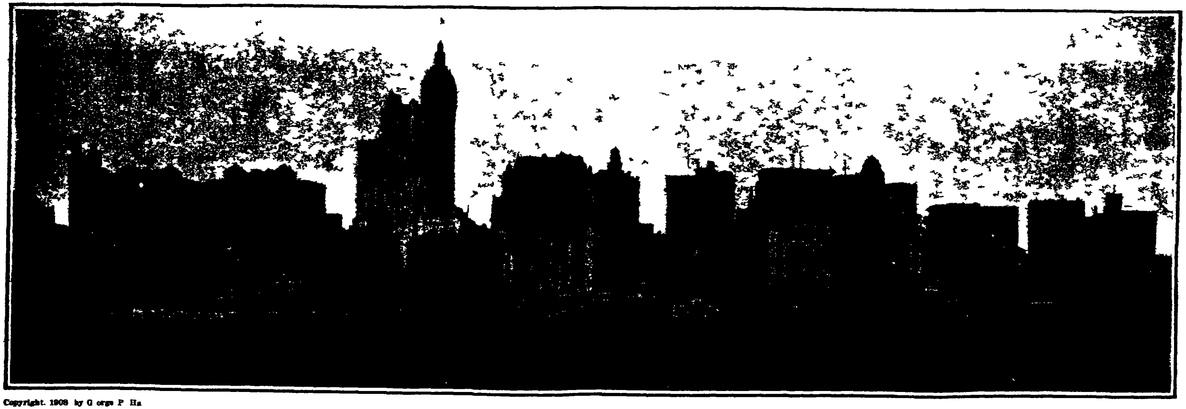
In 1783, when New York was evacuated by the British troops, the condition of the city was most deplorable. The streets, which had been paved and partly graded before the war, had been suffered to lapse into idle wastes again. The wharves had rotted and all the public and many of the private buildings had fallen into a state of semi-ruin. The population had decreased and the city was practically wrecked. Under the inspiration of the new government the inhabitants revived the city within three years so that the former population was regained and commerce quickly returned.

We have before noted the crookedness of the streets in the lower part of the city especially below the stockade at Wall Street. At the beginning of the nineteenth century nearly all of Manhattan Island down as far as Fourteenth Street was practically a virgin territory which could be treated in any way which seemed conducive to the public good. It was thought to be wise to make a plan which would be so comprehensive that the growth of the city would be provided for for a couple of centuries or more so that an act of the Assembly was passed on April 13, 18[illegible] and a commission of [illegible] enlightened but blundering men was appointed—men who were of great importance for the time—as Commissioners of Streets and Roads in the City of New York. They were given much power and [illegible] to [illegible] somewhat [illegible] in the attainments the results would have been far different. They were allowed four years in which to prepare their plans and fix posts at suitable points. In 1811 they made their reports and their maps were filed which created the city from Houston Street to Washington Heights substantially as it exists to-day. Without doubt their labors were most arduous, as a survey involving the placing of 1,549 marble monumental stones and 98 iron bolts proves. The commissioners had the opportunity to create a most beautiful city instead of the commonplace utilitarian arrangement from which the citizens are now suffering. These worthy men left undone the things which they should have done and did the things which they should not have done. They decided that the beautiful forest growths should be cut down, that the hills should be leveled, streams were bridged over and filled in, and upon the plan thus produced they decided that the city should be built with the aid of the T-square and triangle. As Mr. Janvier says: "The commissioners in their [illegible] was [illegible] questionably gave their [illegible] best thought to the work confided to their indiscretion; the[illegible] by their own showing [illegible] to the height of considering the claims of what they believed to be the beautiful before they decided upon giving place to the useful alone." In regard to parks these excellently dull gentlemen had their own views. They thought that the large arms of the sea which embraced Manhattan Island furnished all the variety required. They would not [illegible] a space to be devoted to parks although they thought that a space should be set aside sufficient for a reservoir. They also felt the need for a space for military exercises, so that the "Parade Ground," which extended from Twenty-third to Thirty-fourth Streets and from Fourth to Seventh Avenues was provided. We have the remains of the "Parade Ground" in Madison Square, and the whole space includes some of the choicest business locations in the entire city. Union Square was a union of the many roads which centered at that point for the transfer of traffic and may be regarded as a "geographical accident." They provided streets which reached as far as 155th Street northward, reaching from the Hudson to the East and Harlem Rivers. The plan of New York as we find it to-day is stupidly commonplace and it has cost millions to give even a semblance of variety to the work of these worthy gentlemen. Among the mistakes which the commissioners made was to provide one-third less to the square mile for longitudinal streets than they did for cross streets. They did not seem to realize that they were dealing with a long and narrow island whereon the traffic would always be in a longitudinal direction, but we are now feeling the stern necessity for increased facilities for north and south travel.

In 1805 the free school system was founded. Prior to that time schooling was largely a matter of private enterprise. Each church had its own school and there were also numerous private schools kept by teachers who were remunerated for their services. The first public school was opened in 1806. A number of scientific and literary societies were founded in New York at the beginning of the nineteenth century.

Before the days of the steamship and the railroad was the era of the fast "clipper" like those which ran from Baltimore and which were famous for their great size and speed. So fast were they that for many years after steamers were built they maintained a nearly equal fight against their more formidable rivals. Fast vessels made the trip to England in fourteen days. It seems extraordinary that the United States, that during the first half of the nineteenth century brought the art of shipbuilding to such a high plane, should be so neglectful of her ocean commerce in the last half of the century. The more recent events connected with New York city are outlined in the chronology which follows and which has been especially compiled for this issue.

When we look at the impressive picture of the sky line from the City Hall to the Battery there is one point which is of surpassing interest—how was it possible to secure enough ground to permit of the erection of such vast structures, as we know that the original territory comprised in this part of Manhattan Island in the days of Peter Minuit was not so great. When Manhattan Island was first purchased from the Indians there was doubtless little thought that it would ever be necessary to increase the area of the seemingly large island. From the beginning, however, we find examples of made land, of docks being



Copyright, 1908, by George P. Ha[illegible]

THREE HUNDRED YEARS LATER—THE SKYLINE OF THE HUDSON RIVER SHORE FROM CITY HALL TO THE BATTERY WITH THE SINGER BUILDING OUTSTRIPPING ALL IN HEIGHT built of ponds being filled up, and a general tendency to increase the superficial area. In former times the island was very much narrower than at the present time although the general shape was the same The old maps show the lower part of the island extending in width barely from Broadway to the present Pearl Street

Since olden times filling has gone on along the city edge for generation after generation, until many blocks have been added, and the island has been increased by the addition of area on its outer periphery precisely in the place where the addition counts the most. Originally, the junction of Pearl Street and Maiden Lane marked the entrance of a wide canal, and another wide canal ran up Broad Street beginning at Front Street and extending nearly to Wall Street. These facts indicate the narrow limits of the old city

The rapid currents of the Hudson and East Rivers, especially the latter, had to be guarded against, and as early as 1654 it was resolved to drive planks into the shore, and to make uniform sheet piles between Broad Street and the City Hall for the lower part of the city and many other ordinances touching on the subject of the water front were passed

The map gives us a good idea of the enlargement of the city area It is only within modern times that the limit of enlargement has been fixed and bulkhead and wharfhead lines located to determine the extent to which filling and dock building operations may be carried out. The map in the shaded portions shows the original limits of the lower end of the island, while in outline are given the additions up to the present time Along the water front on this ground which has been reclaimed from the rivers are built many lofty and heavy structures which are very noticeable in our view of the skyline of New York

EVENTS IN THE HISTORY OF NEW YORK ARRANGED CHRONOLOGICALLY

1609	The arrival of Henry Hudson on the "Half Moon"
1613	A trading-post was established on Manhattan Island by Dutch merchants.
1621	The Dutch West India Company was chartered
1626	Peter Minuit buys Manhattan Island of the Indians for $24
1635	Fort Amsterdam completed
1652	The first city charter granted
1653	A palisade was built along "Wall" Street
1656	First city survey
1658	The streets were paved with stone and guarded by watchmen
1664	The Dutch dominion surrenders to English rule.
1683	Printing press set up by William Bradford
1696	Building of first Trinity Church
1697	Streets were lighted
1699	City Hall built in Wall Street.
1707	Broadway was paved from Bowling Green to Trinity Church
1725	New York Gazette established by William Bradford
1730	Stage line to Philadelphia opened.
1731	Fire department was organized.
1763	Jersey City ferry was established
1766	St Paul's Church was built.
1774	The Hoboken ferry was established
1776	Battle of Harlem Heights Washington occupies New York
1783	Washington bids farewell to his officers.
1789	Meeting of the First Congress. New York was the federal capital Washington was inaugurated
1790	First laying of sidewalks.
1807	First voyage of the Clermont." St John's chapel built.
1811	The Commissioners of Streets and Roads in the city of New York finished laying out the present city
1812	City Hall finished
1814	Steam ferryboats were put in operation,
1817	Erie Canal was begun, and first line of packet ships established.
1819	The first ocean steamship "Savannah" was built.
1825	Gas was introduced, and Erie Canal was completed.
1833.	The New York Sun was founded.
1835	Founding of the New York Herald
1836	The Erie Railroad was begun.
1841	The New York Tribune was founded
1842.	Old Croton Aqueduct was opened.
1845	SCIENTIFIC AMERICAN was established
1846	Electric telegraph line was opened between New York and Philadelphia.
1848	Founding of Collins Line of steamships
1851	New York Times founded.
1853	World's Fair
1856	The site of Central Park purchased
1857	Cooper Institute founded
1858.	Opening of Atlantic cable
1860	New York World founded.
1862.	Building of the "Monitor"
1870	Old Brooklyn Bridge begun.

Aeroplane Flights During the Hudson-Fulton Celebration.

For the first time since the invention of the aeroplane New York will be given an opportunity to witness sensational flights by the leaders in aviation Those flights will be made by Wilbur H Wright and Glenn H Curtiss with their respective biplane machines Up to the time of our going to press, Mr Wright had not stated just what feats he would try to accomplish after he has made his initial flights during the present week above Governor's Island Sheds have been erected upon the island for the machines of both aviators. Mr Curtiss, who arrived from Italy last Monday after having won the Brescia Grand Prix 31-mile race in 49 minutes, 23 1/5 seconds, has signed a contract to fly up the Hudson from Governor's Island to Grant's Tomb and back, and Wilbur Wright will doubtless make fully as remarkable flights, above the waters of the lower bay In one of these Mr Wright will probably remain an hour or more in the air Mr Charles F Willard who as mentioned in our last issue, has been making flights above Lake Ontario, will perhaps make flights with the Aeronautic Society's Curtiss biplane There is also a possibility that a new monoplane, built by a member of the Society, may make flights An elaborate system of signaling has been arranged, whereby the people will be quickly notified when flights are to be made.

America Boiled Down.

In the year of our Lord nineteen hundred and nine, we find the United States the most progressive country of the world Its growth has been more than remarkable, and one who wants to boast of his country need only secure a copy of the "Statistical Abstract," a document issued each year by the Department of Commerce and Labor

This particular publication, originated some thirty years ago in the Bureau of Statistics under the direction of John Sherman, then Secretary of the Treasury, and which in its first issue was a thin pamphlet, has grown to be now an unwieldy volume crammed from cover to cover with masses of figures. At a glance such a document would seem very dry for summer reading, but after one has delved into it, the comparison in the growth or decrease of everything is fascinating

To-day the population of the United States is in round numbers 88,000,000. Last fall 14,887,133 individuals lined up at the polls to cast a vote for a Presidential nominee, And the last figures obtainable show that six thousand four hundred and sixty-six millions of letters and postal cards were sent through the mails. The table does not state whether the greater quantity of this fabulous number were post cards or not. At any rate, the quantity is two-thirds as much as the combined postal business of Great Britain, Germany, France, and Austria-Hungary, and twice as great as any one of them, notwithstanding the fact that France has the reputation of being one of the greatest letter-writing countries. The people, however, had a great many things to say quickly, and becoming fidgety over the "slowness" of the mail facilities, used slightly over one hundred million telegraph blanks, in order to relieve their nerve tension and get quick results.

Of the 88,000,000 of population, practically one-third are domiciled in the thirteen original States, another third in the States created from the territory ceded to the common union by those States, and the remaining third in the area added by purchase or annexation.

It is interesting to observe that our total continental area, including Alaska, is about equal to that of all Europe, that while the area conceded to the thirteen original States by the peace treaty of 1783 was 828,000 square miles, their present area is but 326,000 square miles, forming in part or in whole thirteen other States, while the remaining twenty-four States and Territories were created from territory added by purchase.

Uncle Sam has some resources left. There is just 754 000,000 acres of land still left in his keeping though it may be mentioned that all of it is not very desirable Almost half of this acreage is in Alaska, and much of it in the Rockies. He also has other resources besides vacant lands. In his charge there are 52,827 water wheels to be kept turning, but there is plenty of power for that purpose, for he is credited with having 5,360,000 horse-power from streams with which to keep them moving

The estimated coal supply of the country is 3,135,708 000,000 tons, and during the last year almost a half a billion tons were mined The iron-ore supply of the United States is nearly five billions of tons, 52 000 000 tons being the amount mined for the last year reported. The wealth of the country in 1850, according to the figures available, was $7 000 000 000, speaking in round numbers, in 1890 it was $65,000,000,000, and the last figures show it to have jumped to $107,500 000,000. The last report shows that the wealth production of farms amounted to $7,412,000,000, alone more than the wealth of the country half a century ago

There has been a steady decrease in the negro population since the year 1810, the percentage in that year being 19 03 In 1850 it was 15 68 per cent of the total population, in 1860 14 12 per cent, and so on Last year the percentage was 11 59

Out of his $107,500,000,000 Uncle Sam spent during the last year just $197,000,000 for school teachers. The United States imported one and a half billions of dollars' worth of products, according to the latest figures, but half that amount was raw material for manufacturing The exports amounted to nearly two billions of dollars, about forty per cent of which represented manufactured goods.

This mass of boiled-down information presents a picture of conditions in the United States which is extremely interesting, not merely to the economist and student, but to those interested in the growth of the country

The Current Supplement.

The current SUPPLEMENT, No. 1760, opens with an excellent illustrated article on a German automobile fire engine, which has been adopted by the German city of Frankfort-on-the-Main The recent improvements in the internal-combustion engine are reviewed by H E. Wimperis. Among the economies practised in machine shops, foundries, and metal working establishments of various kinds, few are more suggestive than the use of magnetic separators. The principal applications of these as thus far developed, will be found excellently outlined in an article entitled "Magnetic Separators for Various Uses." Prof A F Ganz's admirable summary of recent electrical progress in the artificial lighting field is concluded. Efforts have been made from time to time in the past to produce the Egyptian types of cotton in America. The latest of these efforts is described by Charles Richards Dodge Ernest Rutherford's brilliant paper entitled "Visualizing the Atom" is concluded. Though Nature evidently meant the vertebrates to be a tooth-bearing race, her design has by no means been rigidly adhered to, as many creatures of very different orders have been permitted, so to speak, to adopt various substitutes therefor Mr W P Pycraft interestingly describes these various substitutes. Dr D. T Macdougal's paper on "Aridity and Evolution" is concluded.

◆

Prime Minister Asquith recently announced in the House of Commons that the British government would recommend a Parliament grant of $100,000 to Lieut. E. H. Shackleton, in order to defray the expense of his recent expedition. If the appropriation is made, Lieut. Shackleton will be out of debt. When he returned from his expedition, he found that he owed $315,000. With the assistance of his friends he succeeded in paying all but $70,000, which last sum he hoped to earn by writing, and by lecturing in the United States.

DEVELOPMENT OF THE HUDSON RIVER STEAMBOAT.

(Concluded from page 217)

the development of the river steamboat had been carried at that early date. Both boats had return-flue iron boilers, and when pushed to their highest speed would burn from twenty-three to twenty-five cords of wood per trip. The rivalry between the two became so great that finally a formal race from New York to Albany was decided upon, and on November 8th, 1836, they started abreast of each other at 4 P M with everything tuned to the highest pitch. The 'Rochester" reached Van Wies Point, 140 miles from New York, in eight hours and fifty-seven minutes, and the "Swallow' five minutes later Some interesting details are given by David Stevenson in an English work, "Engineering in North America," published in 1838, of a trip which he made on the "Rochester" in 1837, when the distance to Albany was made in ten hours and forty minutes. The steam pressure, according to this authority, was 45 pounds, and the steam was cut off at half stroke. Speaking of the remarkable speed of American steam boats at this time he says the vessels "navigating the Hudson River and Long Island Sound perform their voyages safely and regularly at a speed which far surpasses that of any European steamer hitherto built." A good description was given during this period by a German vistor of a trip made in 1838 on the "North America." He gives the length of the vessel as 200 feet, her beam as 26 feet, and describes her as having two decks, the lower of which was about three feet above the water There were separate cabins for men and women, that for the men being used also as the dining room He writes "There were 320 passengers on board each of whom slept in a berth, and as sufficient room appeared still to remain one may imagine how colossal this floating palace must be" He paid three dollars, or two cents per mile, for the passage In "less elegant" steamboats the fare was one dollar and in some boats as low as fifty cents.

The inventive and original mind of Robert L. Stevens was shown in the design of the "Rainbow," an experimental vessel of very narrow beam, the breadth of which compared to her length was as 1 to 14 She was driven by a pair of inclined condensing engines, one forward and one aft of the wheel, with cylinders 36 inches by 10 feet, coupled to a common crankpin Her boilers, strapped at every 10 inches with bar iron, 1¼ by 6 inches, carried the enormous pressure for those days of 80 to 100 pounds per square inch The hollow wheel shaft, made of ⅝ inch boiler iron was 3 feet in diameter She did not make the high speed expected, and was subsequently used for towing.

The contests of speed which characterized that period were accompanied by rate wars, in which passengers were carried over the full course at rates which at one time dropped as low as twelve cents, and it is recorded that on one occasion rather than see an opposition boat carrying a full passenger list, a rival steamboat offered twelve cents apiece to the public for the privilege of taking them, the deficit being subsequently made up when the ship was under way by the simple expedient of raising the price of meals by 300 per cent.

As evidence of the high state of development to which the steamboat had been carried by the middle of the century, we quote the case of that handsome steamer "Alida," built in 1847 by William Brown of New York. This craft, of which we present an excellent illustration, was 265 feet long, 30 feet broad, and 7 feet deep. She was driven by a steam engine with cylinders 56 inches diameter by 12 feet stroke From the very first she proved to be a "flyer"; and on May 8th she made the trip of 145 miles from Albany to New York, with six landings, in seven hours and fifty-six minutes. was not however the first boat to bring the time below eight hours that distinction belonging to the "South America," which on April 19th 1843 covered the distance in the extraordinary time of seven hours and twenty-six minutes This trip however was made without any landings and the vessel was favored by a heavy freshet in the river which not only gave deep water over the shoals but set up a swift current in the vessel's favor

It is impossible within the limits of the present article to follow in detail the development of the famous steamboats on this famous river There was a steady increase in size though the speed having been carried to the high point of between twenty-one and twenty two miles an hour was destined to remain stationary We can do no more than mention two celebrated boats the 'New World of the People's Line with wheels 45 feet in diameter and a piston of 15 feet stroke and the Francis Skiddy with 40 foot wheels and a 11 foot stroke of piston two vessels which had many struggles for supremacy during the ensuing decade

We pass on to the year 1852 when in consequence of the many deplorable accidents which occurred due to the too frequent bursting of boilers Congress passed a law for the inspection of vessels which put an end to the perilous practice of steamboat racing The stories which have come down to us of the reckless way in which engineers would bottle up their boilers when racing with a rival boat are astonishing but nevertheless well verified Morrison a most careful historian credits the statement of an engineer that on being pressed by his captain to pass another boat he prepared for the contest by tying the safety valve lever drawing the pointer from the mercury gage plugging up the mouth of the tube and urging the fires under the boilers He passed the other boat but we are not surprised to learn that it was his opinion that although ordinarily he carried thirty pounds the pressure during the contest must have risen to fifty or sixty pounds to the inch

It is probable that the Hudson River boat which has attained the most world wide popularity is the Mary Powell of the Day Line which built in 1861 has been in continuous service ever since and is to-day one of the most popular boats on the river Her original dimensions were 260 feet length 34½ feet beam and 10¾ feet depth Her model is particularly sweet with a long sharp entrance and a very easy run Her fastest trip was made from New York to Poughkeepsie 72¼ miles in three hours and thirty nine minutes including the time lost in six landings Deducting this time her average speed while running under full power was 22 04 miles per hour Her present captain A E Anderson a son of her previous owner and captain informs us that during her long life of nearly half a century she has been rebuilt three times and lengthened 40 feet The lines of the original boat however have been religiously preserved Her present length is 300 feet Her original engines had one cylinder 62 inches by 12 feet which was replaced by a cylinder 72 inches by 12 feet stroke in 1874 Steam is supplied by two return flue tubular boilers and she uses a working pressure of thirty five pounds under which she makes the eighteen miles per hour necessary to make her scheduled time Under the forty five pounds which she is allowed this wonderful old craft is still good for twenty miles an hour The hull of the Mary Powell was built by M S Allison of Jersey City and her present machinery by the W & A Fletcher Company of Hoboken

Another wooden vessel famous in her day was the St John 1864 the cylinder of whose engine was 85 inches in diameter with the exaggerated stroke of 15 feet.

The year 1880 was signalized by the appearance of the first iron steamboat, the "Albany," [illegible] the second being the "New York," [illegible] These, with two exceptions, are probably the fastest large passenger steamers plying on American inland waters to-day With their long, unbroken lines, graceful sheer, and triple buff-colored smokestacks, they present as beautiful a marine picture as one would wish to see Both vessels, after being some time in service, were lengthened by the addition of 30 feet, and as thus altered their dimensions are "Albany," 325 feet length by 40 feet beam, and "New York," 341 feet length by 40 feet beam the breadth of both vessels over the guards being 76 feet. The engines are of the typical walking-beam type, with cylinders 76 inches diameter by 12 feet stroke They were allowed fifty pounds pressure, but thirty-five pounds is sufficient to enable them to attain their schedule speed of about eighteen miles an hour The "Albany" holds the blue ribbon of the Hudson River On October 22nd on her way up to Albany for winter quarters, she was given an engineer's trial for speed Leaving 22nd Street at 11 01 A. M she reached Poughkeepsie dock at 3 09 P M thus covering 72¾ miles in three hours and eight minutes at a speed of 23 26 miles per hour On May 28th 1903, the sister boat, the "New York," made the same trip at an average speed of 23 21 miles per hour

In 1906 the Hudson River Day Line placed in service the handsome steel passenger steamer 'Hendrick Hudson," which measures 390 feet over all, 42 feet breadth of hull 82 feet over the guards, and draws from 7½ to 8 feet of water The vessel was designed by F E Kirby of Detroit and J W Millard of New York, who were subsequently engaged by the Hudson Fulton Commission to design the replica of the "Clermont." Including that in the hold the vessel has six decks four of which are available for passenger accommodation These decks are unusually spacious and they can accommodate without crowding five thousand passengers. The dining room has accommodations for 262 persons The vessel is driven by an inclined double-expansion paddle-wheel engine with a 45-inch high-pressure and two 70-inch low pressure cylinders acting on three cranks, the common stroke being 7 feet. Steam is furnished at 170 pounds pressure by eight boilers. The paddle wheels in this vessel as in the "New York' and "Albany," are of feathering type On her trial trip, made over the measured course on the Hudson she made 24 5 miles per hour or about one mile an hour more than the high speed credited to the "New York and "Albany" The latest addition to the Day Line boats is the 'Robert Fulton" built to replace the "New York" which was burned while in her winter quarters The "Robert Fulton" is 348 feet in length 42 feet beam, and 76 feet in width over the guards. She was built by the New York Shipbuilding Company of Camden, N J, and was launched in the record time of two months and ten days after the keel was laid The hull, which is built of steel, is considered by the company to possess the finest model of any of the large steel vessels of the Day Line. She embodies the best features of the model of the "Mary Powell" and other fast boats, and her appearance on the year of the centennial anniversary of Fulton's great work is very timely Her maximum speed is 23½ miles an hour. Our illustrations include one of the "Adirondack," which may be taken as typical of the fine fleet of steamers owned by the People's Line which makes the night trip between New York and Albany These boats differ from the Day Line steamers in their larger size, more moderate speed, and the towering superstructure for the accommodation of the many tiers of staterooms. The "Adirondack" is 412 feet in length, 50 feet in beam, and draws 8 feet of water. Being a wooden vessel, she is strengthened by the two big suspension trusses which are such a characteristic of the American river steamer. She has [illegible]

The Most Useful Adding Machine

is the one that adds multiplies, divides and subtracts—with unlimited speed—and the only such machine is the

ADDS MULTIPLIES Comptometer DIVIDES SUBTRACTS "In A Class By Itself"

Isn't it plain that it necessarily must pay you larger dividends because of its complete range of usefulness and speed? Other machines simply add—one-fourth as useful—and then only half as fast. The Comptometer easily earns its price three to five times each year That is why we want you to try the Comptometer

The Outdoor America Numbers of Collier's

The National Weekly

These Outdoor America Numbers are edited by Caspar Whitney. There is one of them each month, carrying six or eight pages of text and pictures devoted to all kinds of activity in the open air—hunting, fishing, motoring, athletics, gardening, fruit-growing, chicken-raising, and a score of kindred subjects.

The number dated October 16 and appearing on the news-stands at that time is to be a particularly good one, with unusually fine photographs There is an automobile article by Albert Lee, a story about "The Poor Man's Race Horse"—whippet hounds; an article on how to find and track deer, another concerning the use of electricity for light machinery on the farm, and still another—of rare interest—on athletics at the Vatican, with some splendid photographs.

Collier's

The National Weekly

3,800 maximum horse-power, can drive her at a speed of 20½ miles an hour The maximum in size and accommodations is reached in the "C. W Morse," of the People's Line, which is 427 feet over all, 90 feet over the guards, and contains 450 staterooms. The dining room will accommodate at one time 300 people She is driven by a walking-beam engine with a cylinder 81 inches in diameter by 12 feet stroke, and her maxium speed is 20½ miles per hour

In the above necessarily brief story of the development of the Hudson River steamboat, we have endeavored to bring out the salient points of the increase in size, speed, and accommodation of one of the most remarkable and successful types of vessel in the world to-day It would be well in closing to refer to the phenomenal speeds which were achieved by these vessels over half a century ago and draw attention to the fact that their record passages were usually made when wind and tide were favorable The swiftest of the present-day boats would undoubtedly exceed the earlier speeds though by no very great margin and it must be remembered that under existing conditions, they are run under a fixed schedule, generally under a reduced steam pressure and are operated at several miles less speed than the maximum of which they are capable

◆

THE AMERICAN WALKING-BEAM ENGINE

(*Concluded from page 223*)

board side being the steam pipe and the other the exhaust. Each of these pipes carries a separate rocking shaft, which is operated by its own eccentric The motion of each rocking shaft is communicated to two vertical lifting rods, which operate the valves by means of two cams called "wipers" The eccentric rods are formed with hooks at their outer ends which engage a pin in the arms of the rocking shafts. They are thrown out of gear by means of the slotted vertical rods through which the eccentric rods work one of which will be seen in the engraving These vertical rods are known as strippers and they are operated by the levers which will be noticed attached to the rocking shaft on the steam pipe When it is desired to start or reverse the engine, the eccentrics are thrown out of gear, and the valves are worked by a steam starting and reversing engine which is controlled by the vertical lever seen near the steam pipe If it is desired, the valves can be operated by the vertical starting bar shown in the engraving

The handwheel on the small vertical standard in front of the exhaust pipe opens the steam valve for the starting engine, and the wheels which are seen on the other two standards are for operating the injection valve and for turning the surface condenser into a jet condenser, if at any time it should be desired to do so The surface condenser is located in front of the steam cylinder and below the main deck. Behind the steam cylinder and also below the main deck is the air pump which is operated by connecting rods from the walking beam. The gear shown attached to the front face of the gallows frame above the cylinder, is a hand winch for lifting the cylinder head

The paddle wheels are of what is known as the vertical or feathering type, in which the buckets are made to enter and leave the water in a nearly perpendicular position. The old type, with fixed radial buckets, is extravagant and uncomfortable, extravagant because it wastes power in forcing water downward when the buckets strike, and lifting it when they leave the water, and uncomfortable because it sets up a violent vibration throughout the whole vessel The feathering paddle wheel is smoother and more efficient in its action, and its efficiency is from 12 to 15 per cent greater than the older type Its construction is as follows Bolted to heavy timbers just above the guards is a large pin carrying a loose flanged ring to which are pivotally attached a set of connecting rods. At their outer ends these rods are pivotally connected to rocking arms fastened to the back of the buckets the buckets themselves being pivotally attached to the rigid spokes of the paddle wheel The pin and loose ring are placed eccentrically to the crankshaft and the ring is rotated in its proper relation to the paddle wheel by attaching one of the connecting rods rigidly to it. The eccentricity of the ring is so adjusted that the buckets shall always enter and leave the water in a perpendicular position thus securing a true feathering action The wheels are 30 feet in diameter

Steam is supplied by four steam boilers of the lobster return flue type each 11 feet wide 9 feet 3 inches diameter of shell and 31 feet long with steam domes 87 inches diameter and 10 feet 6 inches high Forced draft is supplied by two large Dimpfel blowers driven by independent engines The steam pressure is 55 pounds to the square inch and the total horse-power is 3 800

"A PUTTING ON TOOL"

The DAVIS-BOURNONVILLE PROCESS of Oxy-Acetylene Cutting and Welding Is the

Greatest Invention of the Decade

Progressive Metal Workers

Are adopting it rapidly Our Plants are now being used to great advantage by manufacturers of metal furniture, sash and doors, steel cars, iron and steel pipe, seamless boilers and tanks, electrical apparatus, automobiles, and by iron, steel and brass foundries, for reclaiming castings and very extensively by repair shops for mending broken machinery, engine cylinders and aluminum automobile casings and for building up worn gears and other parts. Our Cutting Torch is invaluable for cutting steel piling and structural iron, and for wrecking steel and iron work

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

ADJUSTABLE PATTERN M [illegible] New York N Y This invention consists in the construction and combination of parts, whereby the different edges of the pattern may be moved outwardly or inwardly substantially in parallelism without varying the relative proportions or the general shape of the pattern Attachments are employed for varying the style of the garment rendering one pattern useful for cutting different forms of garments

PNEUMATIC HEEL CUSHION W I [illegible] Deal N J The cushion is such as worn at the heel of the shoe on the inside in order to cushion the heel in walking The cushion has an improved form which increases its elasticity in action and a further object is to provide improved means for holding the cushion in position

Electrical Devices.

TELEPHONE SYSTEM B T [illegible] Allen Md In this case the invention relates to telephone systems and is particularly applicable to rural mail delivering routes in which the delivery points are relatively far apart It may be used also as a parcel delivering system or for any purpose in which the rapid transportation of slight matter is desirable

HEADGEAR FOR SUPPORTING LIGHTS D F [illegible] Willimantic Conn The gear is for use by surgeons dentists and opticians and supports an electric light and delivers the rays directly upon the object under inspection The main feature involves a spring metal band adapted to extend over the head from the front to the back and is retained in position by resilient engagement with the forehead and back of the head

Of Interest to Farmers.

BEEHIVE J Weaver Fort Worth Texas The object among others here is to provide a hive of concrete or cement whose walls will be thick enough to exclude heat and cold and whose interior will be large enough to receive any desired form of honey frames and which will afford at its entrance ventilating means cleaning out means and means for the passage of the bees into and out of the hive

PEA HULLER W L Hay Franklin Tenn The intention of this inventor is to provide a device of comparatively simple construction in which the hulling of picked peas or of peas on the vines may be accomplished by merely shifting the concave and feeding the peas through the device in the direction most suitable for their proper treatment

DEVICE FOR TEACHING MILKING P J DeVries Hull Iowa The purpose of the improvement is to provide a device that simulates the udder and teats of a cow pendent therefrom together with other details that afford means for practising the removal of water from the artificial udder by a proper compression of the teats and thus acquire the art of milking quickly and safely

Of General Interest

SOLDER FOR ALUMINIUM J L [illegible] — Rue d Bagnolet Paris France This solder is not easily broken and it readily resists the action of acid and water It may be used for soldering pieces of pure aluminium or of the alloys thereof or for soldering aluminium upon copper zinc steel and other metals regardless of the general shape and thickness of the parts.

BUTTER AND LARD CUTTER C H Carlson Iron Mountain Mich The invention is an improvement in self measuring lard and butter scoops for use in taking lard or butter out of barrels, tubs, or other receptacles The blades may be made of different sizes to measure different quantities of the material and the blades or other portions of the device may be of any suitable metal or material

DISPLAY STAND.—I. Towle, Oremont, Ga. The invention pertains to stands for postal cards and similar articles, and more particularly to one having a number of leaves or partitions movably supported upon a suitable standard, and having the surfaces perforated to permit clips for holding the cards or other articles to be inserted at a number of points and in different positions.

METHOD FOR PROTECTING GROWING PLANTS AND VEGETABLES.—E. R. Drake, De Land, Fla. In this case the improved method of growing plants consists first in protecting the plant bed on its several sides but leaving the same open and spaced above; next, when the plants have grown to a considerable height raising the protecting parts correspondingly, and also shading the plants along the sides and overhead.

Railways and Their Accessories.

SEAL.—R. A. Finian, Iola, Kan. The device is especially intended for sealing railway cars and the like, and the initials of the railroad or the firm using the seal may be embossed on the annular space between the dished portion and the periphery of the disks. The leaden seal may be impressed with the station number or other suitable designation showing where the seal is placed.

RAILWAY TIE AND RAIL CLAMP.—W. C. Nees, Lakin, Kan. The aim of the invention is to produce a tie having an improved form and particularly adapted to be constructed of metal. A further object is to produce a clamp to be used in connection with a metal tie, and which will operate effectively to hold the rail in position without the use of spikes or similar fastening devices.

CAR-DOOR OPERATOR.—F. F. Unckrich and C. I. Sealey, Galion, Ohio. The invention relates more particularly to a car having a plurality of doors, a controlling member, operable from various points of the car for simultaneously opening and closing the doors, and connections between the members and the doors, parts of the connections being adapted to be inoperably disposed so that the controlling member can be rendered inoperative with respect to any one of the doors.

Pertaining to Recreation.

PUZZLE.—R. D. Clover, Weston, Colo. The present object is to provide a puzzle with an outer run way and inner run way surrounding goals, with gates in the run ways and goals so disposed that considerable skill is required to roll balls from the run ways through the gates and [illegible] respective goals.

GAME APPARATUS.—W. H. [illegible], Mornington, Victoria, Australia. The invention consists in the construction and arrangement of parts constituting a game apparatus. A board or table is provided upon which are placed miniature forts, men, castles, and numerous objects. Toy shooters are provided fitted with spring mechanism adapted to project pins, shots, or pellets through ports from the four corners of the board against the forts, men, and flags.

Pertaining to Vehicles.

DETACHABLE RIM FOR PNEUMATIC OR OTHER TIRES.—M. A. Lamberciel, 112 Rue de Richelieu, Paris, France. In this patent the invention has reference to a detachable rim which allows a complete pneumatic tire fully inflated, or a solid India rubber tire, mounted on said detachable rim to be attached to or detached from the wheel of a vehicle with great rapidity.

CASING FOR PNEUMATIC TIRES.—J. H. Seiberling, Jonesboro, Ind. The casing is arranged to permit its convenient or ready application on either single clench or double clench style of wooden rim, it being provided for this purpose with separable abutting edges and single exterior locking ribs arranged at equal distances from the edges, the portion of the casing extending from the base of each rib to the corresponding edge gradually diminishing in thickness and forming a pliable non-clenching closing flange.

VEHICLE-WHEEL.—W. L. Howard, Trenton, N. J. The invention relates more particularly to the mechanism for rigidly locking the rim in place yet permitting of its ready removal. It is particularly adapted for vehicle wheels having pneumatic tires carried by the rims, the object being to facilitate the removal of the rim and tire and the substitution of a new rim and tire in case of puncture or other injury.

SPEED-GAGE.—O. D. Munn and J. E. Brachvogel, New York, N. Y. The invention is particularly useful in connection with devices intended for measuring the speed of railroad trains, automobiles, and the like. An object is to provide a gage by means of which the speed of moving bodies can be measured with accuracy, and which is insensitive to shocks and concussions. A circulating fluid medium is employed which is sensitive to extremely slight changes in the degree of velocity of the moving body.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

It Fits

There's one paper that is made solely to meet the requirements of the amateur—a paper that has the quality that gives the best results from amateur negatives:—

VELOX

If you do your own printing, Velox will be easiest for you to work because it fits your negatives. If you have a professional finish your work, he can give you the best results on Velox—because it fits your negatives.

There's a wide variety in surfaces, weights and grades.

If your developer and finisher doesn't use Velox, write us, we will tell you of one who does.

SCRIBNER'S MAGAZINE
THEODORE ROOSEVELT'S FIRST AFRICAN ARTICLE
CHARLES SCRIBNER'S SONS NEW YORK

Mr.
Roosevelt's
own account of his
African Trip
(to run a year) will appear
exclusively in
SCRIBNER'S
MAGAZINE

The First Article
A RAILROAD THROUGH THE PLEISTOCENE
in the October Number

describes the start of the famous expedition—the wonderful railway journey through a country that was like a "great zoological garden," the black tribesmen of his caravan, his outfit, guns, tents, his first hunting experiences, etc., etc. The illustrations from photographs by Kermit Roosevelt and other members of the party.

To meet the extraordinary advance demand for these articles the publishers have provided a very large edition of this first number, but it will be well to place your order for a year's subscription at once in order to be sure of obtaining the complete series. Any person who can secure subscriptions can make money on Scribner's this year. Liberal cash commissions and cash prizes. Write NOW for particulars. 25 cents a number; $3.00 a year.

BABBITT METALS.—SIX IMPORTANT formulas. SCIENTIFIC AMERICAN SUPPLEMENT 1123. Price 10 cents. For sale by Munn & Co., Inc., and all newsdealers. Send for catalogue.

A CLEAN, COOL, SWEET
SMOKE WITHOUT INJURY

Tobacco not touched by the nicotine tar which falls to bottom of bowl, nor saliva, which is trapped in bottom of smoke passage. Smoke leaves the stem at top of tip, hence does not draw against tongue. Our invention also makes cleaning easy and ensures a cool, clean and healthful smoke

The Sanitary Pipe

eliminates the objectionable features of pipe smoking without sacrificing appearance or utility. Best quality briar bowls, solid rubber stem, nickel-trimmed. Sent by mail, postpaid, for a dollar bill. Money back if you prefer it to the pipe.

Concrete
Reinforced Concrete
—AND—
Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete by Bryson Cunningham The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J. Jones of the various systems of reinforcing concrete, concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete. Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A. Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley, Jr., on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete, depositing of concrete, facing concrete, wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

JOSH BILLINGS said that "the only thing some underwear is good for is to make a fellow scratch and forget his other troubles."

THAT WAS BEFORE THE DAY OF

Wright's Health Underwear

It is the fleece of comfort, and can't scratch

Keeping out the cold and keeping in the bodily heat is only the beginning of the good work of **Wright's Health Underwear** It stands guard over the sensitive skin, preventing that sudden closing of the pores which causes colds, coughs, and congestion in various parts of the body

Wright's Health Underwear, made by a recent process, of selected high-grade wool, is the best on the market. Yet it is in reach of people of moderate means. Not a fad, just a sensible "loop-knit" woolen garment, lined with the fleece of comfort.

Wright's SPRING NEEDLE Ribbed Underwear

Is a product based upon the need of an underwear with an unusually wide range of elasticity It is knit on patented improved Spring Needle Knitting Machines, which produce a fabric of wonderful elastic properties. It is so constructed that it yields to fit perfectly any form, and when taken off the body resumes its normal shape and size Made in beautiful fabrics of cotton, also wool.

Inquire at your dealer's for WRIGHT'S Underwear and always look for the woven label trade-mark.

"Dressing for Health," a valuable booklet free.

Blame the Strop!

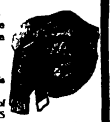
How about the strop behind *your* razor? How about your ability to use it? Is *every* shave a pleasure *now!*

The NEVER FAIL sharpens any razor—does it better and in less time than a hand expert can, and gives the keenest, smoothest cutting edge you ever saw

A Western bank president (name on application) writes "Have used one blade over six weeks, and I shave daily. One box of blades with your stropper should last a lifetime. Wouldn't part with mine for $50"

WILL YOU TRY IT FOR 15 DAYS?

Money back if you want it—ask any bank in this city as to our responsibility.



No. 1—for Safety Blades

Put on the market only four months ago, after years' of experimenting, thousands of NEVER FAIL STROPPERS sent out on trial have triumphantly proved their worth in every state in the Union. The combination of a perfect strop with an infallible automatic action is a real necessity for every man who shaves or should shave. Every consideration of economy and personal comfort urges you to supply yourself today

Every user of safety razors knows that mighty few—if any—of his blades are actually fit to use until they are stropped. The NEVER FAIL will make every one of them good for from 50 to 150 perfect shaves, so it pays for itself in money as well as time saved.

Order by number, with the coupon below.

No. 1—for every style of safety

No. 2—for the old style razor

Four Beautiful Out-of-Doors Pictures FREE!

Do not confuse these with cheap pictures. They sell at Art Stores for 50 cents each.

TO every reader of this periodical who loves nature and animals and out-door life we will send, without charge, four beautiful pictures. They are printed on heavy art paper without lettering, and are wonderful examples of the art of color photography. Framed at moderate cost, they will make excellent decorations for your home; or they can be used just as they are. Size 10½ x 7½ inches.

¶ We send these pictures to advertise our *Standard Library of Natural History*, which has just been completed after years of labor and at enormous expense. It contains over 2,000 illustrations from actual photographs. In many cases these photographs were secured by special expeditions sent to foreign lands for that purpose.

Your application for the pictures will impose no obligation to purchase the Library. Neither will you be bothered by agents or canvassers.

As an evidence of good faith, enclose 10 cents (silver or stamps) for wrapping and postage. This will be refunded if you request it after examining the pictures. When writing, mention this periodical.

Morton R. Edwin

Panatelas

$2.40 per hundred instead of $5.00

By all standards of comparison this is a 10c cigar. It will satisfy the most cranky smoker of imported brands. It is fully 5½ in. long, strictly hand made, of choicest Havana tobacco—genuine Sumatra wrapper. It smokes freely and evenly—never chars down the side but keeps burning coolly and fragrantly to the last toothhold.

The reason this cigar is sold at $2.40 instead of $5.00 per hundred is because I buy and sell for cash. I ask no credit, neither do I give it. I personally buy my tobacco direct from the grower in Cuba and pay him at least five weeks before the tobacco reaches the U. S. Custom House. I buy for less and sell for less. I believe in what Elbert Hubbard said in April, 1907, issue of the *Philistine*:

> "A Credit Account is the most insidious form of borrowing money. When you don't pay the merchant at once for the goods you buy from him, you are borrowing money from him, and disguised in the price is much more than the legal rate of interest. Better to borrow the actual cash and know how much you have to pay for the accommodation; but it is better still to practice self-denial and go without the thing you want till you have the cash to pay for it.
>
> All the losses of the merchants who give credit are made good by the people who pay.
>
> The merchant who gives credit is not in business for his health any more than the pawnbroker is."

Actual Size

Among my 15 different brands I have an "in between" smoke called Old Fashioned Havana Smokers. I want you to be on smoking terms with them because they are just the thing you want when you don't want a big cigar. They are Havana filled—4 inches long—blunt at both ends—made the way the Cuban planter rolls tobacco for his own use without a binder.

I'm so eager to have you try this smoke that I'll send you a sample box of 12 free along with an order for my Panatelas, because you will buy them again.

Send me $2.40 for 100 Morton R. Edwin Panatelas. Smoke as many as you like—smoke them all if you want to and if you then tell me that you didn't receive more than you expected, I'll return your money and we'll remain friends.

If you want to know who I am and whether or not I run my business on the square, if you have any doubts as to my making good if my cigars don't, just inquire from any bank or commercial agency about me. If you don't like the report you get, keep your cash at home.

BLACKSTONE

A BIG PENCIL FOR BIG MEN

Most pencils are made to sharpen, this one is made to write. Blackstones are for men too busy to fuss. You don't care that we mellow the graphite six months, test every lead, use the best Florida cedar. This is a pencil that works all day without tiring your hand. Newspaper men use it. Lawyers use it. Ministers swear by it. Business men and business women owe themselves a trial of it. *Sample sent for 10c. Stationers sell them.*

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 8969.—Wanted machines that make accordion dress plaiting (steam).

Inquiry No. 8977. For manufacturers of machinery for manufacturing denatured alcohol.

Inquiry No. 8980. For the address of manufacturers of mortars and pestles that are used by druggists.

Inquiry No. 8987. Wanted the manufacturers of the Van Winkle Woods & Sons and the Weber power meters.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

Inquiry No. 8996. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

Inquiry No. 8997. Wanted the address of the manufacturers of bread or cake boxes.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

Inquiry No. 9009. Wanted the address of the manufacturer of the "Loech" showcard holder, a device which is held to the outside of a show window by rubber cups.

Inquiry No. 9010.—Wanted to buy a "Restur Halp-a Phone."

Inquiry No. 9013. Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

Inquiry No. 9016. Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

Inquiry No. 9017.—Wanted the address of manufacturers or dealers in marble and plaster or wood pulp for plastering.

Inquiry No. 9018. Wanted, the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9019. Wanted address of The Old Town Canoe Co.

Inquiry No. 9020. Wanted the addresses of the manufacturers of metal novelties.

Inquiry No. 9021.—For manufacturers of machinery for manufacturing alcohol and turpentine from sawdust.

Inquiry No. 9022. Wanted to buy a light, small motor, not exceeding three pounds in weight, including everything in going order.

Inquiry No. 9023. Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

Inquiry No. 9024.—Wanted, the address of parties who can manufacture fire extinguishers of metal.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Three New Interesting Books

The Scientific American Boy at School

By A. RUSSELL BOND

12mo. 320 Pages. 300 Illustrations.
Price $2.00 postpaid.

THIS book is a sequel to "The Scientific American Boy," many thousand copies of which have been sold, and has proven very popular with the boys. The main object of the book is to instruct how to build various devices and apparatus, particularly for outdoor use. The construction of the apparatus is fully described and the instructions are interwoven in a story, a feature which has assisted in making the "Scientific American Boy" so popular and interesting to the boy.

It takes up the story of "Bill" and several of his companions at boarding school. They form a mysterious Egyptian society, whose object is to emulate the resourcefulness of the ancients. Their Chief Astrologer and Priest of the Sacred Scarabeus is gifted with unusual powers, but his magic is explained so that others can copy it. Under the directions of the Chief Engineer, dams, bridges and canal locks are constructed. The Chief Admiral and Naval Constructor builds many types of boats, some of which are entirely new. The Chief Craftsman and the Chief Artist also have their parts in the work done by the Society over which Pharaoh and his Grand Vizier have charge. Following is a list of the chapters:

Chapter I, Initiation; Chapter II, Building a Dam; Chapter III, The Skiff; Chapter IV, The Lake House; Chapter V, A Midnight Surprise; Chapter VI, The Modern Order of Ancient Engineers; Chapter VII, A "Pedal Paddle Boat"; Chapter VIII, Surveying; Chapter IX, Sounding the Lake; Chapter X, Signaling Systems; Chapter XI, The Howe Truss Bridge; Chapter XII, The Seismograph; Chapter XIII, The Canal Lock; Chapter XIV, Hunting with a Camera; Chapter XV, The Gliding Machine; Chapter XVI, Camping Ideas; Chapter XVII, The Haunted House; Chapter XVIII, Sun Dials and Clepsydras; Chapter XIX, The Fish-Tail Boat; Chapter XX, Type Photography; Chapter XXI, Water-Tights and Current Sailing; Chapter XXII, The Wooden Canoe; Chapter XXIII, The Bicycle Sleigh; Chapter XXIV, Magic; Chapter XXV, the Sailboat; Chapter XXVI, Water Sports, and Chapter XXVII, A Geyser Fountain.

Handy Man's Workshop and Laboratory

Compiled and Edited by A. RUSSELL BOND

12mo. 400 Pages. 350 Illustrations.
Price $1.50 postpaid.

EVERY practical mechanic, whether amateur or professional, has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity. The resourceful man who has met an issue of this sort successfully seldom, if ever, is adverse to making public his methods of procedure. After all he has little to gain by keeping the matter to himself and, appreciating the advice of other practical men in the same line of work, he is only too glad to contribute his own suggestions to the general fund of information.

About a year ago it was decided to open a department in the Scientific American devoted to the interests of the handy man. There was an almost immediate response. Hundreds of valuable suggestions poured in from every part of this country and from abroad as well. Not only amateur mechanics but professional men as well were eager to recount their experiences in emergencies and offer useful bits of information in genious ideas, wrinkles or "kinks," as they are called. Aside from these, many valuable contributions came from men in other walks of life—resourceful men who showed their aptness at doing things about the house, in the garden, on the farm. The electrician and the man in the physics and chemical laboratory furnished another tributary to the flood of ideas. Automobiles, motor cycles, motor boats and the like frequently call for a display of ingenuity among a class of men who otherwise would never touch a tool. These also contributed a large share of suggestions that poured in upon us. It was apparent from the outset that the Handy Man's Workshop Department in the Scientific American would be utterly inadequate for so large a volume of material, but rather than reject any really useful ideas for lack of space, we have collected the worthier suggestions which we present in the present volume. They have all been classified and arranged in eight chapters under the following headings:

I, Fitting up a Workshop; II, Shop Kinks; III, Soldering of Metals; IV, The Handy Man in the Factory; V, The Handy Man's Experimental Laboratory; VI, The Handy Man's Electrical Laboratory; VII, The Handy Man About the House; VIII, The Handy Sportsman.

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON

Assistant Secretary Concrete Association of America

12mo. 200 Pages. 150 Illustrations.
Price $1.50 postpaid.

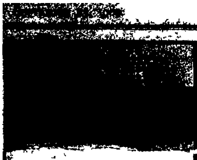
THIS work should appeal strongly to all those interested in ornamental concrete, as the author has taken up and explained in detail in a most practical manner the various methods of casting concrete in ornamental shapes. The titles of the thirteen chapters which this book contains will give a general idea of the broad character of the work. They are entitled:

I, Making Wire Forms and Frames; II, Covering the Wire Frames and Modeling the Cement Mortar into Form; III, Plaster Molds for Simple Forms; IV, Plaster Molds for Objects Having Curved Outlines; V, Combination of Casting and Modeling—An Egyptian Vase; VI, Glue Molds; VII, Colored Cements and Methods Used for Producing Designs with Same; VIII, Selection of Aggregates; IX, Wooden Molds—Ornamental Flower Pots Modeled by Hand and Inlaid With Colored Tile; X, Concrete Pedestals; XI, Concrete Benches; XII, Concrete Fences; XIII, Miscellaneous, Including Tools, Waterproofing and Reinforcing.

The first two chapters explain a most unique and original method of working pottery which has been developed by the author. The chapter on color work alone is worth many times the cost of the book, inasmuch as there is little known on this subject, and there is a large and growing demand for this class of work. The author has taken for granted that the reader knows nothing whatever about the material and has explained each progressive step in the various operations throughout in detail. These directions have been supplemented with half-tones and line illustrations which are so clear that no one can misunderstand them. The amateur craftsman who has been working in clay will especially appreciate the adaptability of concrete for pottery work, inasmuch as it is a cold process throughout, thus doing away with the necessity of kiln firing, which is necessary with the former material. The book is well gotten up, and is printed on heavy glazed paper and abounds in handsome illustrations throughout, which clearly show the unlimited possibilities of ornamentation in concrete.

Send your orders now, and a copy of the book desired will be mailed on the day of publication.

MUNN & CO., Inc., Publishers, 361 Broadway, New York



A Failure at Fifty

Out of a job at fifty—is the fate of the untrained man.

Business requires not only natural ability but special training.

The Trained Man Can Defy Old Age

The American School of Correspondence can fit *you* for congenial, well paid positions in your early years, and make your services valuable in your old age. Training only can compensate for the energy of youth

For thirteen years the School's *Engineering Courses* have set the standard for thoroughness and practicalness in correspondence instruction. The School has trained thousands of men for the technical professions, or has advanced them to higher positions. To-day these courses represent the highest development of correspondence teaching.

The Courses in Commerce, Accountancy and Business Administration

set the same high standard in the commercial world. They prepare for the best-paid business positions; they are prepared by practical business men who have "made good" by practicing what they teach; they are planned to meet the needs of both the young man who is just starting in, and the older man who has almost "arrived"

Get your training now, while you have the time and energy for study Mail the coupon to-day

Government Homesteads

Over one and one half million acres of land open for settlement in Cheyenne River and Standing Rock Indian Reservations, October 4th to 23rd

Registration at Pierre and Aberdeen, S. D.

Direct route to registration points is the Chicago & North Western Ry
Special low homeseekers' round trip rates.

This land is well watered by the Cannon Ball, Grand, Moreau and Cheyenne Rivers and their tributaries. The soil is a light loam, fertile and makes a good grain producing land. The land must be lived on and improved. A low valuation of from 50 cents to $6.00 per acre has been placed on the land by the Government, arranged in easy annual payments covering a period of five years.

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc, 361 Broadway New York

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

The Making of Men

The reasons given by most men for desiring to enter the Navy are "To see something of the world", "to learn a trade", "to save money", and—**"To make a man of myself"**

It is becoming more generally known that the Navy offers a steady, ambitious young man as good opportunities for a future career as he can obtain anywhere. When bluejackets are questioned regarding their opinion of the Navy after a few years' service, their most frequent answer is, **"It made a man of me."**

Navy training develops character Under the Navy system of advancement, the worthy young man's progress is assured He is given greater responsibility, with higher pay as his capabilities increase. Inevitably he develops self-reliance becomes quick and alert, resourceful and confident, with a military bearing and a clear brain—the natural accompaniment of a healthy life and a clean body If the young man does not develop under Naval influences he lacks the qualities to "make good" anywhere

But Navy training alone would not produce this result The young man must come into the Navy with good principles, industrious, of temperate habits, a common school education, and a serious intention to stick to his job whether he likes it at first or not. This is the type of youth the Navy appeals to and shiftless characters need not apply

Look for the address of the Navy Recruiting Office in the want columns of your Sunday papers. If you don't find it, write for illustrated Booklet describing duties, pay privileges, etc., and for instructions how and where to apply Address

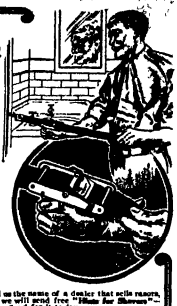
RUNDEL AUTOMATIC STROPPER



Keeps a Perfect Edge On Any Safety Blade

A child can work it. Just push and pull the stropper up and down the strop. Blade is held at correct angle and reverses automatically—can't cut the strop. Then you always have sharp blades without buying new ones. Very economical and convenient—no safety razor complete without it.

Sold on Approval By All Dealers

Try one for 10 days. If you don't wish to keep it, your money is promptly returned. Complete outfit consists of a Stropper, strongly built of brass and steel, nicely nickel plated, and with ruberoid finish handle, Three Blade Holders; and a 22-inch finest quality Horsehide Strop. All are enclosed in a handsome case and sell everywhere for $2.00. If your dealer can't supply you we will send the outfit prepaid.

Rundel Automatic Stropper costs more than its imitations, but it is the only stropper adapted to all style blades—the only stropper scientifically adjusted and controlled—the only stropper that automatically strops exactly like the barber—the only stropper that's made right, works right, and will last for years.

Free Book on Art of Correct Shaving Tell us the name of a dealer that sells razors, and we will send free "Hints for Shavers"—a valuable book just written by an expert barber. Send for it to-day.

We Want To Tell You How

You can save not only the dealer's profits but his excessive charges for installation and repairs by dealing direct with the manufacturer. You can keep in your own pocket at least one-third the retail price of a heating plant. Let us tell you all about the

Jahant Down Draft Furnace

Only $10 down and $10 per month, with freight prepaid east of the Mississippi River. This wonderful furnace has proven its superiority above all others during the last 20 years. It is without doubt the very best heating system for your home. It saves from ⅓ to ½ in fuel bills, because the patented "down-draft" burns hard or soft coal—slack or lignite—without clinkers or cinders, giving full heating value of every particle of fuel. Heats better than any furnace you ever saw. A strong "Guaranty Bond" goes with every Jahant, which allows you a 365 days' free trial of the furnace. You run no risk, as we supply special plans, full directions and give free all necessary tools, so that any man who can drive a nail can successfully install a Jahant. No matter what make or system of heating you are considering, let us tell you about the many convenient and good points of our furnace; it's economy. [illegible] and how you can save money. Write today for our book.

TRUE SIGNIFICANCE OF THE HUDSON-FULTON FESTIVAL.

The splendor of the Hudson Fulton festival stands for greater things than the mere exploitation of two individual men Back of the music and the shouting the blaze of color, the roar of saluting guns, and the blended laudation of press pulpit and platform—back, indeed, of the two men whose names are in every mouth and before every eye are two cardinal facts of world wide and age-long import and endurance, to which we must look for an explanation of the stupendous scale of this festival and the universal interest which it has awakened

Why do we give Henry Hudson such pre-eminence over Gomez and Verazzano and place Fulton above Fitch, Symington, and Stevens?

The transcendent importance of Hudson's voyage to New York Bay and up the river which bears his name is due to the fact that he explored and opened up to the world the great highway of travel which nature had laid down from the Atlantic seaboard to the heart of the American continent Gomez and Verazzano dropped into New York Bay as they did into many another inlet, and probably gave it value as one of several convenient watering places encountered on their coastal voyage.

Although Verazzano made mention of a great river it is evident that he made no exploration to ascertain whether it was a river or an arm of the bay Indeed, the fact that it was saline and tidal must rather have suggested a closed arm of the sea than a noble fresh water river Henry Hudson on the other hand, not only sailed through the river for its whole navigable length but he noted its flora and fauna the appearance and habits of life of the inhabitants and everywhere appears to have made free use of the sounding lead not only throughout the river but in his exploration of New York Bay

And just here we venture the suggestion that, when so astute a man as Hudson had reached the head of navigation he probably made such investigation as sign language and other means of intercourse with the Indians allowed of the nature of the country which lay beyond It is not unlikely that from the Indians he learned of the extensive Mohawk Valley beyond the Hudson of the chain of lakes to the north and of the westward route through which by canoe and portage the travel and traffic of the Indian tribes were maintained from the Atlantic Ocean to the inland seas of fresh water that we now know as the Great Lakes

Bitter indeed must have been Hudson's disappointment when the shoaling of the water just beyond Albany proved to him that his hope of finding a north western strait leading to the Pacific was merely a dream, but his regret was mitigated to no little degree if he realized that he had found a great natural highway into a vast continent of whose extent the Indians probably were able to give him a not unworthy estimate

But setting all mere conjecture aside it is certain that Hudson's careful and intelligent exploration of the Hudson River as distinguished from the cursory and unappreciative glimpses obtained by Verazzano, and possibly by Gomez produced immediate results among the enterprising Dutch traders, and led to the early founding of a city and colony destined to become the most famous and powerful on the whole of the new continent. To the *veni vidi* of Gomez and Verazzano, Hudson added the *vici* of one of the most successful and, in its effects, momentous voyages of exploration that the world has ever known Right worthily does Henry Hudson bear his honors.

The work of Robert Fulton, two hundred years later, was the natural complement of that of Henry Hudson. Because of the inadequate means of transportation the new colony was unable, for fully two centuries, to reap the full fruits of Hudson's discovery of this great highway to the West It is difficult for us to realize the crude condition of travel prior to 1807 There were but few really good roads, the majority were not much better than cleared tracks through the primeval wilderness. Travel by road was laboriously slow, and sailing up or down the Hudson in the cumbersome sloops of those days was little if any, better But the beat of the paddle wheels of the 'Clermont' ushered in an entirely new method of transportation, which was destined to do more for the development of the country in a few decades than had been achieved in the two centuries preceding. The success of the steamboat was one of the causes which led to the construction of the Erie Canal The rapid opening up of the country which followed upon the superior means of transportation thus afforded was exceeded only by that even more swift and complete settlement and exploitation, which followed on the institution of steam railroad travel This in turn followed the same great highway through the Hudson and Mohawk valleys to the Great Lakes and the far West.

Hudson in 1609, and Fulton two centuries later, may have had some glimpses of the ultimate outcome of their respective achievements, but in their wildest flights of imagination did they dream that a thousand ships would join with a city of 4,500 000 souls to grace the scene of their early labors, and render them the present stupendous tribute?

ONE HUNDRED YEARS OF THE MARINE ENGINE.

Reminiscence and comparison will be rife during the week of the Hudson Fulton Celebration, and never will they be more active, surely, than when that curious marine craft, the 'Clermont," slowly creeps under the impulse of her antique engine over the waters of New York Bay and the Hudson River

In the 'Clermont' engine, as in all the Watt engines of that day the low steam pressure of four or five pounds above the atmosphere, was made necessary by the weakness of the copper boilers The pressure being low the condenser was, necessarily, of vital importance, yet the vacuum could scarcely be called satisfactory, for during the trial trip of the replica of the 'Clermont,' we noticed that the vacuum stood at about 22½ inches. Wood was used for fuel, and probably the consumption per horse power per hour was equivalent to not less than five or six pounds of coal

The marine boiler and engine are greatly indebted to the activity of the Hudson River steamship builders for their early improvement We know that compound engines were used on this river as early as 1824 and that they showed satisfactory results. Furthermore steam pressures of as high as 50 pounds to the square inch were used on the Hudson River long before the middle of the last century

The marine engine made slower progress in ocean navigation than on the rivers, and particularly on the Hudson The earliest transatlantic steamers say of the period from 1845 to 1855, used boiler pressures of from 10 to 20 pounds to the square inch, and the approximate consumption of fuel was from 4½ to 3½ pounds per horse-power per hour From 1855 to 1865 when the paddle wheel gave place to the screw propeller the approximate boiler pressures were from 20 to 35 pounds and the consumption of fuel was reduced from 3½ to 3 pounds per horse-power per hour In the ten years, from 1865 to 1875, of the development of the transatlantic marine engine, the compound took the place of the simple engine, and steam pressures rose from 35 to 60 pounds, while fuel consumption was reduced from 3 pounds to 2.2 pounds per horse-power per hour With the introduction of triple-expansion engines during the period from 1875 to 1885 the boiler pressures were doubled from 60 pounds to 125 pounds, and the approximate consumption was reduced from 2 2 to 1 9 pounds per horse-power hour Then, in that notable period from 1885 to 1895, came the twin-screw quadruple-expansion engine, with boilers using forced draft and carrying pressures of from 125 to 225 pounds per square inch. The resultant economies were remarkable, the fuel consumption per horse-power per hour falling from 1.9 to 1.4 pounds per horse-power per hour

Then came the most radical improvement in the marine engine in all the hundred years since the days of Fulton, when Parsons introduced the steam turbine, whose advantages ultimately proved to lie not so much in a further reduction of fuel economy, as in economies of weight, engine room space, consumption of oil, the great reduction of the cost of repairs and general up-keep, and above all in a great increasing of speed Strange to say, boiler pressures, which had been mounting steadily upward, fell from the maximum of 225 pounds, as used with multiple-expansion engines, to about 150 or 180 pounds, which was found to be the most economical pressure for a turbine. The fuel consumption in high-speed turbine vessels is approximately the same as that of the very best reciprocating engines using all the modern contrivances of forced draft, superheaters, etc. Such are the conditions which obtained during the period from 1895 to 1905.

The present decade is being devoted to the development of the marine turbine, by the removal of certain defects, which at present seriously limit its usefulness. As matters now stand, the turbine drive gives its best results only when applied to comparatively high speed vessels, and when they are driven at their maximum power As the speed decreases, there is a loss of efficiency Furthermore, the economical speed for the propeller is an uneconomical speed for the turbine. The present development is in the direction of combining the reciprocating engine with the turbine, using the former for the higher ranges of expansion and the turbine for the lower ranges. This combination gives an engine which can run economically at a low or cruising speed, that can reverse, and that can show as good economy on a cargo steamer as an all-turbine engine on a high-speed vessel

Figures have recently become available of the first ocean-going installation of this kind, which was placed in the cargo steamship 'Otaki" Since her delivery in November, 1908, this ship has completed a voyage to New Zealand and back She is a sister ship, except in her engines, to two other vessels, the 'Orari" and Opawa," fitted with reciprocating engines. The "Otaki" is driven by two sets of triple-expansion reciprocating engines, one on each wing propeller, and a low-pressure turbine driving a center propeller

A comparison of the relative performance of the two ships shows that at the full-speed trial the "Otaki" developed 5,880 horse-power, as against 5,350 horse-power shown by the "Orari' Her coal consumption between Liverpool and Teneriffe was 11 per cent less when steaming under similar conditions and at practically the same speed A comparison of the coal consumption for the whole of the voyage shows a gain for the 'Otaki' of 8 per cent, or 500 tons of coal The engines made a non-stop run from Teneriffe to New Zealand of 11,669 miles The coal consumption, on the run from the Clyde to Liverpool at about half the power, worked out at 1 387 pounds per horse-power for all purposes—a most satisfactory result.

In the steam turbine we have apparently reached the limit of efficiency in the history of the steam marine engine. The indications are that the developments of the future will be in the direction of an internal-combustion engine using either oil or producer gas

COMBATING INJURIOUS INSECTS WITH THE AID OF THEIR NATURAL ENEMIES.

An interesting instance of successful warfare waged against injurious insects with the aid of their natural enemies is reported from Hawaii where the sugar plantations have in recent years been threatened with annihilation by the ravages of a small cicada little more than ⅛ inch long Prof Kirkaldy, the director of the Honolulu entomological station has described the little insect and named it *Perkinsiella saccharicida*. It pierces the stem of the sugar cane and extracts the sap, causing the plant to wither and die The formidable character of this insect pest is due to the amazing rapidity with which it multiplies. Six generations are produced annually and on the assumption that 20 females of each brood live to reproduce their kind, it is estimated that the progeny of one female produced in the course of a single year, numbers 64 millions. The insect was undoubtedly introduced with the sugar cane from other countries into Hawaii, where it has multiplied enormously, as its natural enemies which limit its numbers elsewhere, do not appear to have been imported with it. Entomologists were, therefore, sent abroad to discover the original home of the little cicada, to find its natural enemies, and to bring these to Hawaii It was necessary to extend these laborious and costly investigations to every part of the world from which sugar cane plants had been imported. The home of the insect was finally located in Australia, where two of its most formidable enemies were also found These are two species of ichneumon fly, of the genera *Paranagrus* and *Ootetrastichus*, which lay their eggs in the eggs of the cicada. The first-named species destroys only the cicada eggs in which its own eggs are deposited, but the other species pierces only one egg of each cluster of cicada eggs and its larva destroys the entire cluster Both species have been successfully colonized in Hawaii and the prodigious increase of the sugar cane cicada has thus been checked.

* * *

The first steel steamship ever built in the maritime provinces of Canada is under construction at Yarmouth, Nova Scotia. A great development is expected in this industry, which, in the days of wooden vessels, was such an important factor in the prosperity of the provinces bordering on the Atlantic coast.

ENGINEERING.

The Canadian government has decided to advise the board of engineers to call for tenders for the new Quebec bridge, to take the place of the ill-fated one which collapsed during construction. The span has been reduced from 1,800 to 1,718 feet, and plans are to be prepared for bridges of both cantilever and suspension type, the style adopted depending upon cost and speed of erection and general usefulness as compared with expenditure.

Two suction dredgers built by Messrs. William Simons & Co for use in reclamation work by the Bombay Port Trust, which will add a square mile of land to Bombay, have given remarkable results in their acceptance trials. They are equipped with powerful spiral cutters at the end of their suction pipes, and eat their way into solid blue clay at the rate of 2,700 cubic yards an hour, discharging it 4,500 feet away through a pipe line half of which is floating One of them has made a cut 300 feet wide at the bottom, 21 feet deep, and 1,000 feet long in 85 actual dredging hours.

Bids have been opened on the U S battleships "Arkansas" and "Wyoming" and announcement of the letting of the contracts is expected These will be the largest battleships in the world, the plans calling for 26,000 tons displacement 545 feet over-all length 93 feet beam 29 feet draft, and 33 000 horse-power engines, giving a speed of 21 knots. Since the British "Dreadnought" set the fashion in all-big-gun battleships, the size and gun capacity of each new ship of the U S. navy have been steadily increased, but these will be the first two ships to exceed all records of foreign navies The Cramps made the lowest bid of $4 450 000

The steamship "Otaki," built by Messrs. Denny of Dumbarton, is the first merchant vessel to be fitted with "combination" engines consisting of two sets of triple-expansion reciprocating engines driving wing propellers and a low pressure turbine driven by their exhaust steam driving a central propeller The act of reversing the reciprocating engines closes their connections with the turbine, which is not reversible, and diverts their exhaust to the condenser Otherwise the "Otaki" is identical with the sister ships "Orari" and "Opawa" of the same company, fitted with reciprocating engines. On a recent round trip to New Zealand the "Otaki" made the same average speed as her sister vessels with a coal consumption of 11 per cent less than their mean, and a water consumption nearly 20 per cent less, their boilers being identical with hers. She also made a non-stop run of 11 669 miles probably the longest continuous run yet made by a marine turbine.

Some interesting tests of timber under long-continued loads by Mr H D Tiemann of the Yale Forest School were described by him in a paper read before the American Society for Testing Materials The test specimens were continuously loaded in some cases for a year or more, and their deflections under load recovery under partial release of load and other behavior automatically recorded As in the case of ductile metals a curious effect due to plasticity is noticed, which while allowing the timber to be distorted and even to take a set does not affect its ultimate strength The deflections or recoveries due to immediate addition or removal of loads are independent of the deflections or recoveries due to time effect of dead loads. A remarkable relation between the moisture absorbed and the strength of the beam was also shown increase of moisture in the atmosphere causing the test specimens to increase in deflection and decrease in strength to the point of failure

Engineering and building construction for earthquake countries is discussed in an interesting and authoritative manner by Prof. W H Hobbs in the current Engineering Magazine The article summarizes the results of a number of investigations resulting from the California, Italian Japanese, and other earthquakes, showing the lessons learned from practice in localities especially subject to earthquakes as well as from laboratory experiments with materials. It has especial interest in reference to the suggested liability to damage by earthquake of the Gatun dam and locks at Panama. Whereas it is shown that alluvial filled and other unconsolidated formations, especially when marshy afford more dangerous building sites than solid rock near the surface on account of the tendency of the latter to dissipate a shock, it appears that considerable displacement of underlying rock will hardly appear at the surface of overlying loose material if the latter is sufficiently deep. It is further shown that on such loose material rigid buildings, especially when supported upon massive monolithic foundations, are less liable to damage than more elastic structures. It would therefore appear that the deep alluvial deposit in the old river bed under the Gatun dam, much talked of as a danger spot in the construction, represents as safe a foundation as possible in an earthquake country for the massive monolithic structure of the locks and dam.

AERONAUTICS.

On September 21st, Hubert Latham attempted a flight with his "Antoinette monoplane at Berlin One wing touched the ground twice with considerable shock; then a wheel collapsed and the propeller was broken After repairs had been effected, however, he succeeded, on September 24th in making a splendid flight of 1 hour and 8 minutes' duration

In addition to the World's $10 000 prize for the quickest flight by an aeroplane or dirigible from New York to Albany, the American has offered a prize of $1,000 for a circuit of Manhattan Island by an aeroplane. Three airships are ready to start in the first mentioned contest, these being the dirigibles of Capt. Baldwin John Roeder and George L Tomlinson The start will be made from 119th Street and the Hudson River

The flights of Wilbur Wright and Glenn H Curtiss above New York Bay and the Hudson River during the present week are to be the leading feature of the Hudson Fulton Celebration The flights will be announced by flag signals displayed from the Singer and Metropolitan towers, and by bombs, as follows White flag with red center—weather favorable flight will probably take place in the afternoon Black flag with white center—weather unfavorable, no flight to-day White flag with red center over red flag with white center—flight will probably take place within the hour Red flag with white center over white flag with red center—flight will take place within 15 minutes The same with black flag with white center below both—flight has started

At Morris Park late in the afternoon of September 23rd, Charles Crout made a short flight of 60 feet at an elevation of about eight feet with a new biplane built by François Raiche a member of the Aeronautic Society This is the first aeroplane built by a member to succeed in getting off the ground It was run along the track at a speed of 15 to 18 miles an hour against a 12 to 15-mile wind when the flight was accomplished The balancing planes were not operative and the aeroplane tipped in alighting and damaged one end of the lower plane Exhibition flights will be made soon with this machine throughout the country The aeroplane has been acquired by the Scientific Aeroplane and Airship Company which will conduct the exhibitions with it and also with several monoplanes which the company has produced

In the course of his exhibition flights recently at Berlin, Orville Wright made several new records On September 18th, with Capt. Englehardt as passenger he flew 1 hour 35 minutes and 47 seconds thus beating by 23 minutes and 11 seconds his previous record with a passenger During this flight he sent his machine beyond the limits of the Tempelhof parade ground and soared over the railroad tracks and houses in the vicinity In a subsequent attempt during the same day to beat the speed record, the water circulation of the motor gave out, and he was obliged to descend after a flight of 1 hour and 24 minutes. A few days before Orville Wright flew at an estimated height of 50 meters above a balloon anchored at a height of 175 meters thus making the altitude he reached probably over 750 feet Rougier on the 20th ultimo attempted to break this record at Brescia Italy with his Voisin biplane He succeeded in making an official record of over 198 meters (650 feet) Mr Wright will probably fly at the aviation meeting at Berlin during the present week after which he will go to England, in order to test the first Wright aeroplanes built there for the British government

The day following his arrival from Europe, Glenn H Curtiss, the winner of the Bennett aviation trophy and the present holder of the SCIENTIFIC AMERICAN Trophy as well, was given a luncheon at the Lawyers' Club by the Aero Club of America Among the distinguished guests present were William Marconi, the inventor of wireless telegraphy and St Clair McKelway editor of the Brooklyn Eagle The latter told of a trip to Goshen N Y back in 1867 in Andrew's dirigible, an account of which was subsequently published in the SCIENTIFIC AMERICAN This airship (which was made to travel in any desired direction by means of long inclined planes between the triple, parallel cigar-shaped gas bags the planes causing the balloon as it rose from the buoyancy of the gas, to ascend upon a long incline) on this occasion traveled as far as Goshen N Y (50 miles) whence it was blown back by the wind across Long Island Sound to the eastern end of Long Island where a successful landing was accomplished In view of his exploit 42 years ago in this, the first dirigible balloon Mr McKelway believed himself to be the oldest aeronaut present. The mayor of Baltimore, Md read a telegram announcing the flight of Lincoln Beachy from that city to a point in the Blue Ridge Mountains, 125 miles away—a flight which is probably the longest ever made in America with a dirigible balloon The aeroplane with which Mr Curtiss won the Bennett trophy will be exhibited at Wanamaker's store in New York this and the coming week.

SCIENCE.

The record of altitude in aeronautics has been attained by Sig. Piacenza and Lieut. Mina, in an ascension made from Milan on August 10th, 1909 Their great spherical balloon the "Albatross," carried 2,600 pounds of ballast at the start and reached an elevation of 38,700 feet or more than 7 miles. The aeronauts experienced a temperature of —25 6 deg F and landed near Milan 3½ hours after they started

The great tidal waves observed at Marseilles on June 15th, 1909, appear to have been caused by the unusually high electric charge of the atmosphere which is known to have existed during the period of the earthquakes which devastated the south of France The powerful attraction exerted on the surface of the earth by this electric charge caused earthquakes on land and tidal waves in the Mediterranean

Prof. Percival Lowell has noted at his Flagstaff Observatory that the antarctic canals of Mars are disappearing This waning of the much-discussed canals seems to be a well recognized phenomenon Long ago Prof Pickering suggested that we see not really the canals but rather the vegetation which fringes their banks The waxing of the canals in spring and summer and their waning in autumn and winter is not unreasonably attributed to the growth and decay of this vegetation

In accordance with the resolutions of the last International Congress of Mining and Metallurgy Applied Mechanics and Practical Geology held at Liége in 1905 it has been arranged that the next Congress shall meet at Düsseldorf during the last week of June 1910 under the auspices of the Rhenish Westphalian Mining Industry An influential committee of organization has been formed which is charged with the making of the arrangements for the reading and discussion of papers, visits to places of technical interest and social entertainments

A letter has been received at Harvard Observatory from Prof E B Frost director of the Yerkes Observatory stating that Halley's comet was observed visually by Prof S W Burnham with the 40-inch telescope, on September 15th 21 h 39 m G M T in app R A 6 h 18 m 51 1 s and app Dec +17 deg 9 min 44 sec The comet followed B D +17 deg 1232 by 12 7 min, north 4 min 12 1 sec The comet was also photographed with the 2 foot reflector on September 15th and 16th by Mr Oliver J Lee A second letter received at this observatory from Prof Frost states that the comet was also observed visually by Prof E E Barnard on September 17 d 21 h 1 m 30 s G M T in app R A 6 h 19 m 0 9 s and app Dec +17 deg 9 min 0 8 sec The comet followed A G 2122 (=+17 deg 1232) by 0 min 22 55 s. north 3 min 28 9 s Description 15½ mag 12 s diameter with possibly a faint nucleus or indefinite fleck of light in it The comet was also photographed by Mr Lee at the same time

The astronomers of Lick Observatory have been making some spectroscopic studies of Mars from the top of Mount Whitney This peak is the highest in the United States its altitude being 14 501 feet above sea level The instrument taken by the observers was a 16 inch horizontal reflecting telescope to which a suitable spectroscope was attached Of the seven nights spent by the men on the summit only two were clear enough for observation The spectrum of Mars was compared with the spectrum of the moon It is known that there is no water vapor on the moon certainly in no appreciable quantity If no difference can be detected between the spectrum of Mars and the spectrum of the moon under these most favorable conditions *it can be said with safety that water exists* on Mars in negligibly small quantities The results of this expedition have not as yet been published Readers of this column of science notes will doubtless remember that Mr Slipher of Prof Lowell's staff claims to have obtained spectroscopic evidence of the existence of water vapor on Mars

On July 26th, 1909 the Singles coal mine in the French district of Puy de Dome was the scene of an accident similar to that which occurred some time ago in the Gard mines At the Singles mine an interior shaft was being sunk for the purpose of determining the depth of the deposit. This shaft was sunk from a horizontal gallery which led from the foot of a shaft 1 000 feet deep The explosion of a powerful blast shattered the rock and caused the disengagement of great volumes of carbon dioxide, which filled the gallery and both shafts before all the miners could take refuge in the safety chamber This mine possessed no oxygen life-saving apparatus and the manager was absent at the time of the accident The life saving corps of several mines in the vicinity responded promptly to appeals by telephone but no effective work could be accomplished until several hours had elapsed Of twelve miners who had been entrapped seven had passed the day in terror in the safety shelter but the remaining five were found suffocated in the gallery.

HOW WE GET STANDARD TIME

BY HARLAN T STETSON

Although it may be generally known that the determination of time is the work of the astronomer yet doubtless few people stop to investigate the precise methods employed in the correction and distribution of standard time It is a system in itself quite indispensable to the success of the industrial world

The great universal timekeeper is the earth itself So uniform is the earth s rotation on its axis that the length of the day according to Newcomb has not altered the 1/100th and probably not the 1/1000th part of a second since the beginning of the Christian era The direct effect of this rotation is the apparent revolution of the celestial sphere or the daily motion of the sun stars and planets across the sky As places on the earth are determined by latitude and longitude so stars are located by right ascension and declination Every conspicuous star has its position carefully determined and from a star catalogue the astronomer knows at once the instant of culmination or meridian passage of any given star If then with a suitable instrument an observation of a star s transit across the meridian can be obtained and the time of its occurrence be noted by a clock or chronometer a comparison with the catalogue will disclose the amount by which the clock or chronometer is fast or slow Such an operation of finding the clock error is always what astronomers understand by the expression obtaining time The instrument used for making these observations is known as the transit instrument and consists essentially of a telescope so mounted as to be capable of swinging about a horizontal axis in the plane of the meridian The accompanying illustration shows such an instrument ready for the observation In the eye-piece of the telescope is placed the reticle comprising a number of spider webs of which the attached diagram shows five to be stretched vertically and two horizontally across the field of view The instrument is so adjusted that the middle one of the vertical threads coincides as nearly as possible with the imaginary circle in the sky called the meridian

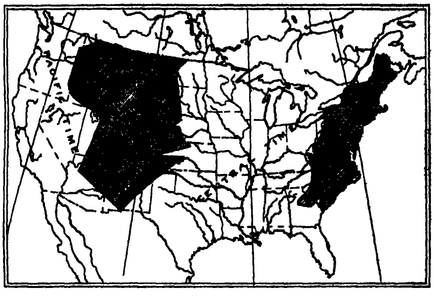
When observations are to be made for determining time the astronomer first turns to the *Ephemeris or some catalogue of stars* and selects a star which is soon to culminate then from the declination he mentally calculates the altitude at which the star will transit By means of a reading circle attached to the instrument he sets the telescope at the proper angle so that the star will pass through the field of view Either of two methods may now be employed in making the observations The first and older of the two is known as the eye and ear method This consists of watching the star pass through the field and while listening to the half second beats of the chronometer estimating to the nearest tenth of a second the time at which the star crossed each thread of the reticle In the chronographic method now much used the mind has less to do and hence more accurate results can be obtained Here as before the astronomer watches the passage of the star across the threads of the reticle but instead of estimating the time of transit he presses a telegraphic key at the proper instant The key is in electrical connection with an instrument called a chronograph and an automatic record is made of each observation Either method will leave a record for the five threads similar to the following the Roman numerals designating the number of each thread in order of observation

I			16 7
II			25 5
III			34 3
IV			43 0
V	7h	9m	51 7s
Mean	7h	9m	34 24s

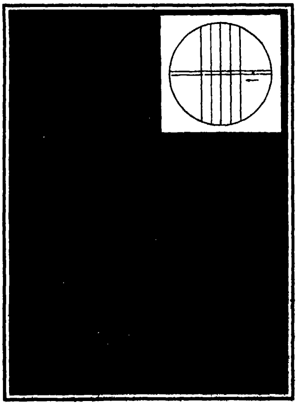
The above is the actual result of a set of observations made by the writer using the eye and ear method The figures in the seconds column were written immediately after the transit of each thread the hour and minute were filled in at leisure after the last observation

The mean of these observations will give a more precise result for the transit over the middle thread than a single observation could afford The exact right ascension of the star we will suppose to have been known as 6h 58m 39 94s which equaled the correct time of the star s transit The chronometer, however recorded the time of transit as 7h 9m 34.24s, and was therefore fast by the amount of 10m 54 30s.

Were the instrument in perfect adjustment and were there no personal element to enter into the result such a set of observations would be quite sufficient. As a matter of fact, however there are always small errors in the instrument which must be determined and applied as a correction to the final result The astronomer therefore does not rely wholly upon a single record like the above but will usually repeat the observation with a number of different stars on the same night From these numerous records he is able to deduce the necessary corrections and thus obtain a more accurate value for the chronometer error Time thus determined ordinarily correct to within one tenth of a second is *sidereal* time and though very useful to the astronomer is quite unsuited to the use of the world in general whose activities are governed by the rising and setting of the sun and not the stars Sidereal time must therefore be converted into *solar* time This is easily effected by a simple calculation constantly employed by the astronomer Having then obtained solar time there remains only to distribute it to the outside world



STANDARD TIME BELTS OF THE UNITED STATES



AN OBSERVATORY TRANSIT INSTRUMENT FOR DETERMINATION OF STANDARD TIME DIAGRAM SHOWS RETICLE OF TRANSIT

Until within the last twenty five years each community used its own local time but as travel became more extensive it was found quite inconvenient to alter one's watch and system of time reckoning for every few miles of traveling east or west. Accordingly, in the year 1883 the United States adopted the present system of standard time. The whole country from the Atlantic to the Pacific was divided into time belts of [illegible] [illegible] belt, [illegible] of the 75th meridian, which is very nearly [illegible] Philadelphia, and is five hours slower than [illegible] time. Crossing into the "Central" belt, watches are set one hour earlier, as the time employed is that of the 90th meridian six hours behind Greenwich time. Similarly, "Mountain" time uses the 105th meridian, seven hours behind and the "Pacific" belt adopts the 120th meridian time, just eight hours slower than that of Greenwich Such a system is quite indispensable to railroad lines, and hence standard time is sometimes called "railroad time" At present almost every civilized country is using some system of standard time usually under the control of its own government.

The chief source for standard time in the United States is the Naval Observatory at Washington D C Here high-grade clocks are carefully regulated by observations of the stars at night, and all necessary corrections applied. For the five minutes preceding noon of each day, eastern time the Western Union and Postal Telegraphic companies suspend all ordinary business and throw their lines into connection with the Washington Observatory It is so arranged that the sounders all over the lines make a stroke each second during the five minutes until noon except the twenty-ninth of each minute the last five seconds of each of the first four minutes, and the last ten seconds of the fifth minute then follows the final stroke at exact noon. This affords many opportunities for the correction and setting of timepieces throughout the country The Western Union Company also operates a system of some 30 000 clocks which automatically set themselves by the noon signal each day

In addition to the Washington signals many smaller observatories determine and distribute time in a similar way to jewelers and local railroad lines In most of the larger seaports time balls are dropped at noon, and give mariners an opportunity to correct their chronometers Fire alarm companies aid in the distribution of time in many localities by sounding bells at certain specified times each day thus affording the public a convenient source of correct time with a reasonable degree of accuracy

---

The Destruction of Rats with Carbon Disulphide.

M de Kruyff of the agricultural bureau of the Dutch Indies at Buitenzorg Java has published an interesting article on the destruction of rats The various contagious diseases which have been recommended for this purpose have been found useless in the tropics and have not always proved effective even in the temperate zone Hence De Kruyff's experiments will be of general interest After working four years with numerous viruses without succeeding in creating an epidemic or even killing a single rat De Kruyff obtained more encouraging results by employing carbon disulphide in the following manner All visible ratholes were first stopped with earth for the purpose of ascertaining which holes were inhabited for the inhabited holes were found reopened on the following day Half a teaspoonful or less of carbon disulphide was poured into each of these holes and after waiting a few seconds to allow the liquid to evaporate, the mixture of vapor and air was ignited The result was a small explosion which filled the hole with poisonous gases and killed all the rats almost instantly A pound of disulphide costing about 16 cents, is sufficient for more than 200 ratholes; 131 dead rats were found in 43 holes which were opened after the operation In two cases, 10 rats were found in a single hole.

The process is, therefore very cheap and its results are immediate and absolutely certain.

It is calculated states a contemporary, that the United States is producing the following per week for fifty-two weeks in the year for every man, woman, and child of the population of ninety millions: Three-quarters of a pound of wire, more than three-quarters of a pound of rails, half a pound of structural [illegible], three-quarters of a pound of plates, [illegible] of a pound of sheets, three-quarters of [illegible] tin-plate, two and a half pounds of [illegible], four pounds of [illegible] castings. [illegible] iron and steel products [illegible] in thirteen pounds each [illegible]

[illegible] OF SHIP CONSTRUCTION

The interest of the shipping world has been aroused by a new departure from the ordinary lines of ship construction, as exemplified in the steamship Monitoria, which recently left the Hylton shipyards of Messrs. Osbourne Graham & Company of Sunderland This vessel of 3,200 tons marks a new development in shipbuilding design being built upon what is known as the *Monitor* or corrugated system For several years past experiments have been carried out by the Monitor Shipping Corporation of Newcastle-on Tyne to determine the best method of increasing the longitudinal strength of a ship without any corresponding increase of weight To this end the underwater part of the hull between the light and load lines was corrugated for almost the entire length of the vessel Continued investigation and experiment resulted in ascertaining the definite form of this corrugation and at last it was resolved to test the system practically in a full sized vessel The Eri sson Shipping Company of Newcastle-on Tyne undertook to build a craft on these lines and the Monitoria now on her first trip was the out ome The vessel measures 279 feet in length by 40 feet 1½ inches normal extreme breadth increased by the Monitor projection to 42 feet with a molded depth of 20 feet 7½ inches

In the accompanying illustrations the forms of construction of the corrugation are clearly shown The shell plating is swelled out in two places on either side longitudinally the curve being somewhat flat and the upper and lower edges curving gradually into the flat side of the normal vessel The main frames measure 8 inches by 3 inches and the depth of the corrugation is 11¼ inches at the crown Plain angles are attached to each main frame and a corrugation gusset plate at each frame There are no side stringers.

The very important result is obtained in this design that the projections give considerable increase in the hogging and sagging strength so that the stress on the material is reduced at both keel and gunwale The construction of the sides of the ship with these corrugations is rather an addition than a vital alteration of the main structural system and it can be applied to any type of steamship The builders claim that the extra cost is slight and the dead weight carrying capacity is increase l from three to four per cent The coal bill is reduced from 1 to 1ɔ per cent for the same speed or if the coal onsump ion is maintained as before the speed f the shi with the extra dead weight is in rease l from 0 2? to 0 knot according to the size and class of the ship

These corrugations in rease the stiffness and longitu linal strength of the vessel

THE MONITORIA —A CORRUGATED SYSTEM OF SHIP CONSTRUCTION

THE GABET WIRELESSLY-CONTROLLED AUTOMATIC TORPEDO

On Wednesday June 23rd experiments were made with the wirelessly controlled torpedo of Gabet to which reference has already been made in these columns In the experiments on the banks of the Seine endeavors have been made to control the torpedoes from a small boat about 100 meters (328 feet) distant from them co taining a plat t for produ ing Hertzian waves

The torpedo motor was started and stopped at will and the rudder turned in every lirection at the will of the man in the boat

The improved Gabet torpe lo onsists mainly of a large cylinder term nating in two cones and forming the low r part of the apparat s Some distance al ve about 1 meters (feet) there is another similar ylinder or ly smaller and inten led to float The lower shell is 9 6 meters long (31 feet)

The two tubes are fastened together by a series of very strong steel tul frames Besides these two other shafts rather large in diameter start from the l wer body exten l beyond the float and form two ather short vertical masts Each o e of these arries an acetylene light They are onne ted by a copper wire

Let us now examine the parts omposing the lower shell whi h is the most important It is divided into sev ral com artments having each its parti ular use

The first compartment is situated in the fore part of the lo er shell It ontains the explosive charge and controls a warl ead similar to the warheads of all present-day t rpedoes whi h produce the explosion of the charge nstantly o ta t with a h d body such as the h ll of a vessel

While all ordinary torpe loes ar ly to 100 kilos of explosive (1 4 to) pou ls e Gabet can take 9)0 kilos (1 98 pounds) with orrespondingly greater destr ictive effect

The Gabet torpedo contains an inter al o nb istion motor operated by gasoline a de ie l novelty Compressed air as now used in torpe motors may supply powerful engines but the radius of action is very

[illegible] torpedo.

The wave-transmitting apparatus set up in a small boat

THE GABET WIRELESSLY-CONTROLLED AUTOMATIC TORPEDO limited The speed of torpedoes thus operated reaches 30 knots, or about 50 kilometers an hour

It is manifestly very dangerous to shut in a gasoline motor in a confined space or nearly so, as is the case here where communication with the outer atmosphere takes place only through the upper part of the foremast.

Ventilation is effected by means of a large blower, situated aft, between the motor and the chamber containing the storage batteries The precautions taken seem sufficient to dispel all fear of serious accidents

The motor is located in the compartment aft of the torpedo It is therefore entirely separated from the explosive charge with which it cannot communicate by any manner whatever

The torpedo used for the present experiments develops 30 horse-power It has a motor with eight cylinders arranged in V shape But the compartment is large enough for a 300-horse-power multiple-cylinder motor, which is necessary to impart to the torpedo the estimated speed of 20 knots, or about 36 kilometers an hour

Regarding weight, every necessary margin is allowed since the torpedo can carry 1 800 kilos (3,960 pounds) of ballast under present conditions, that is to say with a 30-horse-power motor This ballast represents the difference between the weight of an electric motor with its storage batteries and the weight of the internal-combustion motor developing this power

Gabet expects to attain a 10-knot speed with the 30-horse-power motor which he will use in his preliminary trials before putting in the 200-horse-power motor on which he relies to obtain the 20 knots that he considers sufficient speed

Endeavors have been made to obtain for this dirigible torpedo all the advantages that could be had on a real vessel In particular, it was sought to fit it with the means for maneuvering and altering the speed This problem seems strangely difficult of solution The trouble has been overcome by using a reversible screw with which it is only necessary to turn the blades so as to diminish their effectiveness on the water this promptly reduces the speed. By this means a propeller is obtained that acts as well moving forward as backward when given the same speed of rotation

There was another great difficulty to surmount before this screw could be used The power exacted from the motor varied considerably with the speed It became necessary therefore to find a way of reducing the power developed by the motor and of providing against its running away as the resistance of the propeller tended to diminish

To attain this end the spark is retarded as the speed of the torpedo is reduced The motor speed is thus gradually changed by the variation of the pitch of the screw This variation of pitch of the propeller has been availed of to act upon the timer of the motor

For that purpose the pitch-controlling mechanism has been connected with the timer by a jointed rod so that the spark advance is at its maximum when traveling full speed forward or backward The pitch controlling mechanism is also connected to the throttle valve in order to simultaneously diminish in certain proportions the volume of gas admitted

The third compartment of the torpedo contains a small storage battery This is not intended to drive the torpedo but to operate a relay that helps maneuver the boat under the influence of the Hertzian waves acting on special devices

The compartment back of the explosive charge contains the Hertzian controlling instruments They are sufficiently effective to act even at as great a distance as 8 to 10 kilometers (5 to 6 miles) from the transmitting station This distance is a convenient one at the present time for warships get into action at least at 7 or 8 kilometers (about 4 miles) away

We have said that the two masts of the torpedo carried acetylene lights These serve to show the position of the torpedo at every moment, and indicate clearly every change in its course.

It is absolutely necessary to know what is going on inside the torpedo and what influences may act upon it. For although the receiving instruments of the Hertzian waves have been made as perfect as possible, they may come under the influence of other waves than those sent from the transmitting station. In this case, the torpedo would obey other agencies and would deviate from its course

To remedy this serious objection lanterns have been disposed about to flash signals in such a manner that the operator placed on shore or on a ship, may recognize the nature of the directions received by the torpedo. In short every time the torpedo receives waves registered by its instruments, the lanterns show signals to indicate the direction of the torpedo If these signals lead the operator to believe that the waves come from the enemy he does what is necessary to rectify the course of the torpedo, and he nullifies the disturbing waves

We presume that the wireless control of the torpedo remains as we have previously described it. The reader interested in that phase of the construction is referred to SCIENTIFIC AMERICAN SUPPLEMENT No. 1650.

◆

THE "ZEPPELIN III." AIRSHIP AND ITS TRIP TO BERLIN.

The large photographs of the latest Zeppelin dirigible reproduced on our frontispiece this week give an excellent idea of this new leviathan of the air, which made its first long-distance flight from Friedrichshafen to Berlin a little more than a month ago.

The start of this memorable journey occurred at 4 35 A. M on August 27th. The airship started against a light northeast wind. Besides Engineer Durr and young Count Zeppelin (the nephew of the inventor), only three mechanics were carried The crew was reduced to but five men because of the uncertain weather and in order to reduce the weight carried as much as possible. The airship arrived at Ulm at 6 45 A. M., having made the 80 kilometers (49 7 miles) in two hours and eight minutes, at an average speed of about 23 3 miles an hour This speed was maintained up to Heidenheim, a place located on the frontier of Wurtemburg and Bavaria, which was passed at 7 30 A. M. Soon after Gingen was reached. The airship remained here about an hour and described circles, while all the time it was fighting against the contrary wind blowing from the direction of Wurtemburg Soon after Engineer Durr sent a telegram stating that the airship would be forced to land at Nuremberg, on account of a cracked cylinder in one of the forward motors in the forward car On account of this mishap, the speed was reduced considerably, the airship finally arriving at Ostheim near Gunzenhausen 21¾ miles from Nuremberg at 11 45 A. M. At this point a broken propeller—which was immediately replaced by an old one that was carried on board—made it necessary to land Advantage was taken of the landing to renew the water ballast. After a delay of 2½ hours, the airship started again at 2 10 P M for Nuremberg which was reached at 4 45 P M A landing was effected against a strong wind Before landing the dirigible described several circles, in order to give the 120 soldiers of the Fourteenth infantry regiment time to make preparations for anchoring it. When the airship alighted, the crowd broke bounds, and it was feared that they would damage it. Fortunately however, this fear was not realized

The start from Nuremberg was made the following day at 2 15 A. M At 4 A. M it passed above Bayreuth where it was buffeted by the wind for three hours. Engineer Durr dropped a card at 7 o clock stating that all was well on board. At 8 o clock the airship, still battling against the wind, returned to Bayreuth. It then resumed its journey, but was able to make a mean speed of only 14 kilometers (8 7 miles) an hour It passed Muuchberg at 9 40, Hof at 10 o clock, and Plauen at 12 10 P M It was making only 30 kilometers (18 64 miles) an hour Werdau was passed at 1 45 P M and although the wind had completely died out, the speed of the airship grew less and less It was hoped that it would reach Leipsig by 10 P M, when another accident occurred One of the blades of the propellers broke and it was only with the greatest difficulty that the airship was able to reach Bitterfeld It arrived at this place at 6 45 P M, having been driven from Ellemburg by a single motor A successful landing was effected

Repairs were made during the night, and the next morning at 7 30 A. M. the airship left Bitterfeld in a heavy fog. The fog dissipated rapidly, however, and when the airship arrived above the Tempelhof parade ground at Berlin at 12 30 P M., the weather was clear The Emperor and the other members of the royal family were on hand to receive Count Zeppelin, who had gone aboard his airship at Bitterfeld Emperor William introduced him to Orville Wright, and this meeting of the two champions of the heavier-than-air and the lighter-than-air type of flying machine was decidedly novel The landing of the airship occurred above the parade ground at Tegel, after it had first performed evolutions above the Tempelhof parade ground and afterward flown over the city of Berlin. One of our photographs shows the airship above the city, and the other shows it just before alighting.

The return voyage was started at 11 30 P M. the same day The airship followed the Wittenberg-Justerbog railway line for a considerable distance, when it again met with another accident, due to the breaking of a propeller The blade tore through the envelope of the airship, and punctured one of the balloons. The accident happened near Bulzig, about 60 miles from Berlin and with the aid of some farmers, the airship was immediately brought to land in a field near the railroad track. The speed up to the time of the accident was extremely slow, and barely reached 20 kilometers (12 43 miles) an hour Count Zeppelin was not on board at the time of this accident, he having returned to Friedrichshafen by rail. The airship was obliged to remain at Bulzig for nearly three days. It was not until 10 53 A. M. on the morning of September 5th that another start was made. Ulm was passed at 7:55 P. M., and Biberach at [illegible] P. M. The airship finally arrived at Friedrichshafen at [illegible] the following morning after a continuous voyage of 22 hours and 37 minutes. The average speed maintained from Bulzig therefore was only 14 3 miles per hour.

After the "Zeppelin III." had been repaired, an effort was made to sail it to Hergentheim, 120 miles from Friedrichshafen, to take part in the maneuvers; but the repairs were not finished in time, and the airship was unable to reach its place until the maneuvers were over Considerable excellent work was done, however, by the "Gross II" military dirigible at these maneuvers. This dirigible was able to reconnoiter from a great height and to send messages to the rear Emperor William was greatly pleased at the work done by this airship at the maneuvers.

The "Zeppelin III" is the largest and most powerful airship which Count Zeppelin has yet built. It has two 150-horse-power motors, each of which drives, by means of belts, two two-bladed propellers. These are located one on each side of the airship about a third of the way up from the bottom They are held upon brackets projecting out from the rigid frame. The driving of the propellers by belts is a new arrangement, as heretofore they have been driven by shafts and bevel gears. The stabilizing fins near the rear end are somewhat different from before, there being two upon each side placed above the center horizontal line of the airship. The up and down steering is accomplished by quadruple horizontal rudders on each side of the airship at the front and at the rear Besides this, water ballast is carried in a long tank connecting the two cars.

It is planned to use this airship for carrying passengers in different cities in Germany in the near future.

◆

The Current Supplement.

The opening article of the current SUPPLEMENT, No 1761, discusses the San Salvatore mountain railway of Italy Beautiful views of this picturesque road are published. The classification of chemical elements, in the light of Mendelejeff's great generalization, and in the light of the electronic theory, is considered by Prof H. E. Armstrong in a thoughtful paper A critical *résumé* of Prof Wood's experiments with rotating liquids used as mirrors is presented A perpetual clock is described by Charles E Benham A new system for the electrical transmission of pictures is described by Dr Robert Schoenhoefer Prof Albert F Ganz's paper on recent electrical progress in the artificial lighting field is concluded The great rise which is announced in the price of India rubber tires directs attention once more to the various and conflicting problems presented by the wheels of motor cars. These are critically considered Prof William H Pickering presents his view of the origin of meteorites, and advances the theory that meteorites are of terrestrial origin The disappearance of the Bosgoslav Islands is described Sir Norman Lockyer, the well known English astronomer has made a special study of the astronomical value of ancient temples. The result of his researches is presented in an article entitled "The Uses and Dates of Ancient Temples."

The Death of Robert Hoe.

Robert Hoe, senior member of the well-known firm of R. Hoe & Co, printing-press manufacturers, of New York city, died in London on September 22nd, at the age of seventy Mr Hoe was for years the head and front of the extensive business founded by Robert Hoe in 1803 His devotion to the enormous enterprise with which his name was connected, was exhibited not only in an administrative capacity, but also in the suggestion of many improvements in printing presses. His invention of the rotary multi-color and half-tone web presses, now found in every newspaper and job printing plant, is perhaps his most important contribution to the printing art. Mr Hoe was the author of several books, most of them dealing with printing. Among them is a history of the development of the printing press from the time of Gutenberg down to the present day

◆

The railway from the Piræus to the Turkish frontier (246 miles) may be said to be practically completed, the section from Bralo to Larissa having been opened to traffic since October last, and trains now run in twelve hours from Athens to Larissa. The construction of the final section of 28 miles to the frontier is in an advanced state. There remains, then, in order to release Greece from the isolation which she is the last of European States to suffer, but 70 miles between the frontier and the nearest station on the Ottoman railway system. There appears no indication, however, of any disposition on the part of the Ottoman government to facilitate the construction of the junction line, and it will be regrettable if the [illegible] government of Turkey continues to oppose a project so evidently appertaining to an era of civilization and progress.

On Waterproofing Concrete.

On account of the number of inquiries received from correspondents as to methods of waterproofing cement blocks or monolithic concrete, the SCIENTIFIC AMERICAN has been investigating what is being done in the way of improvement of existing methods.

The Concrete Association of America has conducted a valuable series of experiments and distributes its findings free of charge in a public-spirited manner, but the results obtained are largely negative.

Some preparations are found to be effective under certain conditions, but none hitherto has been found to be equally reliable with all mixtures and under all circumstances.

The need and requirements of external paint for concrete, if only to counteract the variable porosity which cannot be avoided unless the personal equation in concrete mixing is eliminated is so well put in a paper read before the recent convention of the American Society for Testing Materials, by Mr G D White, that we quote a part of it by permission

"Unless extreme care is exercised in the preparation mixing, and workmanship of concrete for solid or reinforced work which is not always commercially possible the resultant concrete is not impermeable or at least not uniformly impermeable to water or moisture. Where perfect materials have been used with perfect workmanship we have another difficulty, another problem to solve Concrete is a non-conductor of heat It is, naturally, a cold blooded animal The difference in temperature between the concrete wall and the atmosphere (the warmer the day the greater the difference in temperature) causes a condensation of moisture on the surface This is annoying and a detriment to health in living and office rooms a loss of room or loss by damage in storerooms and warehouses, an objection in any building, no matter what its nature or purpose

"Hollow concrete blocks, tiles brick etc have various defects They are not only porous but capillary positive, and thus absorb moisture from 5 to 40 per cent of their own weight Due to rain and snow walls built of these materials become water-soaked, and remain soaked for varying lengths of time During certain seasons of the year and especially in some sections of our country they remain soaked for months.

"The fact that dry walls are essential to health and comfort is generally known and so well appreciated that the question of dampness has been a restraining agent to a much larger and more extensive use of concrete by the building trades of this and other countries

The tendency to stain the frequence of efflorescence, and difference in color due to difference in materials and to intermissions in concrete are defects of a less serious nature

"A drawback that includes concrete in all forms is the uninviting, unattractive color Replace our buildings of marble of terra cotta, of granite of wood handsomely decorated, with buildings of concrete, and note the contrast The dirty gray of ordinary cement or concrete becomes monotonous to the observer even where there is but a sprinkling of concrete among buildings of more pleasing construction

"If to the strength cheapness, durability, and fire-resisting properties of concrete can be added impermeability to moisture and decoration we will have a building material as nearly perfect as the world has ever seen, and this within the means of every builder

"In recognition of this fact, various concerns and individuals have placed on the market and recommend as a solution to the problem, various treatments and coatings.

"For the sake of convenience, I will divide these into four classes In my investigation of the various treatments and materials included in these classes, I have endeavored to be unprejudiced, and to give to each its true worth and full value.

"I. WATERPROOFING COMPOUNDS IN LIQUID OR POWDERED FORM, MIXED WITH THE CONCRETE IN ITS PREPARATION

"This is a help in that it lessens and retards, in a measure, the moisture-absorbing tendency of concrete. It fails in the desired attainment for the following reasons

"Improper distribution, which is difficult of regulation.

"When properly distributed, it does not render concrete entirely impervious to moisture

"It has a tendency to weaken the tensile strength of concrete.

"It does not decorate.

"The increase in value is not proportionate with the increase in cost.

"It deteriorates with age, that is, a concrete block containing the waterproofing compound, on the first application of water will absorb certain varying quantities. On subsequent applications, allowing the block to dry in each instance, larger quantities are absorbed.

"II. TREATMENTS PREPARATORY TO THE USE OF LINSEED-OIL PAINTS.

"Treatments in various forms have been advanced and recommended by some of our leading master painters, and indorsed by most able research chemists. For the sake of brevity, I have included in my paper but three of these treatments

"(a) Hydrochloric or muriatic-acid wash.

"(b) A wash consisting of a solution of zinc sulphate and water

"(c) A wash consisting of ammonium carbonate and water

"From a chemical standpoint muriatic acid, no matter in what strength nor what the character of the concrete, is not only useless as a remedy, but detrimental in its action Master painters who have endeavored to put it in practice have discovered to their sorrow a confirmation or a demonstration of the chemical theory

"Theory favors and practical tests confirm as the best adapted to the purpose, the former of the two latter methods"

The author proceeds to give the chemical reactions of these various washes with the concrete ingredients, and shows in a convincing manner the reasons why they fail in their desired object He adds

"The treatment with zinc sulphate or ammonium carbonate, even though successful does not offer a solution to the problem because a linseed-oil paint is unsuited for either exterior or interior painting of concrete The gloss robs the surface of the appearance of stone or masonry Linseed oil has water-absorbing and lacks water resisting properties. It cannot be applied over a damp or wet surface which means that following a rainstorm or rainy season a painter must wait weeks and perhaps months before he can commence work on or complete a contract already begun

"III COLORLESS LIQUID COATINGS

"Certain of these may be of some value or service in retarding moisture absorption and efflorescence but they are all alike found lacking in the following respects

"They serve to emphasize any defects in or difference in color of concrete construction

"They impart to concrete a soggy water-soaked appearance

"They do not render impermeable to moisture for any length of time

"They do not decorate"

Under his fourth heading Mr White summarizes paints for concrete with the practical conclusion that there are none which fulfill all the requirements of a severe list which he gives. The principal of these are that it must be applicable to a wet surface and at the same time waterproof when set it must be applicable to the concrete without previous treatment of the latter durable economical and pleasing to the eye must act as a bond between concrete and a plaster coat and remain hard in the presence of water In addition to possessing all the qualifications of ordinary paint such as working well under the brush filling voids and leveling up irregularities of surface

Although Mr White did not say in his paper that he knew of any satisfactory paint we have reason to believe that he has been instrumental in the production of one, or at least that it has been developed with a special view to fulfilling the requirements outlined in his paper

We have recently seen tests, and the results of long-continued tests of a paint called Cementhide which seems to fulfill all the exacting conditions above referred to

At a cement block factory in Newark, N J a part of the process consists of the curing of the newly made blocks by subjecting them to steam for thirty six hours, accelerating their setting and providing a much more constant and uniform supply of moisture to the cement than can be obtained by spraying

For this purpose two curing rooms are used, each of which is opened to be emptied and refilled on alternate days, the steam being turned off in the morning and on again at night. The steam is therefore continuously applied to the interior of the walls for 36 hours out of every 48 The rooms themselves are built of concrete blocks, and were formerly constantly saturated with moisture It was evident from the outside which room was filled with steam from a thin film of moisture trickling down the exterior of the walls, which had to be drained away Six months ago the interior was painted with two coats of Cementhide and now there is no evidence of moisture on the outside of the walls, while the interior has a smooth hard surface differing little from that of well-finished cement except in its pleasant color

Blocks made as identically as possible from one batch of concrete have been tested under varying conditions, one plain and the other painted The unpainted block was found to vary in weight with the water, absorbing it according to the amount present in the atmosphere or from the ground, while the weight of the painted block varied not at all. Blocks painted in a variety of pleasing colors have been left exposed to sun, rain, and wind for months without being apparently affected Concrete painted with this material takes a plaster coat better than natural concrete, both concrete and plaster adhering to the paint more firmly than they do to each other It has even been shown that the rise of moisture by capillarity in monolithic concrete set in moist ground is stopped by a coat of Cementhide between the top of the underground concrete and the masonry or other concrete continuation upward of the wall The paint has a dull finish not unlike the concrete itself, but smoother and of any color desired, and appears to remain hard and to preserve the surface of the concrete indefinitely One cannot imagine a more severe test in any ordinary building than that imposed at the block factory above mentioned and it would seem that this paint should have widespread possibilities when it is sufficiently introduced on the market.

THE MODERN ICARUS

BY JOHN ELFRETH WATKINS

Tradition asserts that the first to sacrifice himself to the problem of flying was Wang Tu a Chinese mandarin of about 2 000 years B C who having had constructed a pair of large parallel and horizontal kites seated himself in a chair fixed between them while forty-seven attendants each with a candle ignited forty-seven rockets placed beneath the apparatus But the rocket under the chair exploded burnt the mandarin and so angered the Emperor that he ordered a severe paddling for Wang

Then there is left in stone a partial account of experiments by Mau U an Assyrian priest who attempted to fly from the temple of Baal The next victims of aviation whom we find are certain criminals whose arms and legs the ancient Leucadians annually fitted with wings of various design and who were then hurled from the Rock of Sappho s Leap" a boat awaiting them in the sea below to give them liberty should they succeed in solving the problem

The first fatality of the kind in our era seems to have been a Roman who during the reign of Nero attempted to fly high in the air over the Eternal City During the Dark Ages one Dante while trying to fly with a pair of wings at Perouse fell upon the top of St Mary s Church and broke his leg The Prior of Tongland in 1510 before the Court of Stirling donned feathered wings and leaping from a tower of the castle fell into the 'mydding' (dunghill) Allard a tight rope performer was crippled by a fall while trying to fly before Louis the Grand at Paris about 1660

Thus far all such accidents were results of attempted aviation for the balloon was not invented until 1783 when this new vehicle of the air met with an accident in Philadelphia during some experiments by Rittenhouse and Hopkins who after sending up dogs and cats in a cage carried by a captive bunch of 47 hydrogen balloons persuaded James Wilcox a carpenter to trust himself in the cage After floating over the city he found himself drifting toward the Schuylkill River and becoming terrified lest he should descend into it, punctured some of the balloons Coming to earth with a thump he broke his wrist

The next victims, Pilatre de Rozier and M Romain set out from Boulogne in 1785 in a car supported by a fire balloon underneath a hydrogen balloon with which compound arrangement they expected to cross the English Channel In a quarter hour when at a height of 3 000 feet the apparatus took fire and the scattered fragments were found upon the seashore along with the awfully mangled bodies of the aeronauts. Next Olivari ascending from Orleans, in November, 1802, also met death by his balloon catching fire

In April 1808 M Mosment ascended at Lisle waving a flag decorated with the imperial eagle of France and the assembled spectators shouted with delight He dropped an animal attached to a parachute and it came safely to the ground Later a murmur of horror rolled over the crowd which learned that in one of the ditches outside the city M Mosment had been found lifeless and covered with blood The same day the balloon came down seventy miles away

In July four years later the corpse of Bittorff after his balloon had caught fire was found stiff and cold upon the roof of a house outside Mannheim Shortly afterward Count François Zambeccari tried, like Rozier and Romain to combine the fire and gas balloon but after adding flame to powder he crashed down from the heavens his body charred and mutilated being picked up near Boulogne

Mme Sophie Blanchard widow of a French aeronaut made an ascent July 1819 in the presence of a vast crowd from the Tivoli Garden Paris, setting off fireworks as she rose Suddenly a great flash was seen above her basket and the crowd thinking this to be a part of the display, shouted 'Bravo' But the flames were seen to spread and the balloon to come down Her basket caught against the projection of a roof and spilled her out upon the pavement where she was picked up dead

The first military martyr was Lieut Harris of the British navy who in May 1824 while studying the strategic value of balloons attached to warships was dashed to earth and killed by the breaking of a valve in his balloon And in September of the same year

Windham Sadler going up from Blackburn England was dropped to his death near Bolton his balloon having collided with a chimney.

When John Wise greatest of all American balloonists abandoned his muslin balloon in 1836 for the "Meteor" wrought of silk he went up in it from Lancaster Pa on a showery day in May. He sailed to the southward and was soon lost in a big black cloud. That night he descended near Port Deposit Md and mooring his balloon near a farmhouse aroused the family. It was drizzling and he was discharging the gas from the upper valve when someone brought a light exploding the gas in the heavy atmosphere. Wise was thrown back ten feet severely scorched and some of those gathered round were badly burned. Wise was taken to Philadelphia where he recovered.

In July 1837 an immense crowd gathered in Vauxhall Gardens London to see an aged savant Robert Cocking test his new parachute. It was of Irish linen had a circumference of 107 feet and was fastened below the basket of a balloon wherein two aeronauts were stationed. Mr Cocking got into the smaller basket of the parachute and the big balloon after taking him slowly up drifted gracefully away. But a rider following on horseback arrived at a field near Lee in Kent just in time to find the dead body of Cocking who had fallen through the air a mile in the collapsed parachute.

Another victim of the parachute was Letur killed in 1854 while attempting a descent and soon afterward Arban of France while rising in a balloon from Barcelona was blown into the Mediterranean and lost. Then in 1850 Gale made a fatal flight while in 1863 Chambers was suffocated by balloon gas in England.

In 1873 at Ionia Mich the populace cheered as the brave aeronaut Mountain rose from their midst in his big balloon. He floated gaily aloft at first but suddenly the fastenings of his basket gave way and he fell from such a height that his body penetrated the earth for some distance.

And next came the first recorded fatality from winged flight since the Dark Ages. Vincent de Groof renowned as the "flying man" while giving an exhibition at London in July 1874 fell suddenly to earth where his corpse was picked up with the stilled wings attached.

In 1875 [illegible] Croce-Spinelli and Sivel two French savants while attempting to break the record for altitude in their balloon "Zenith" rose so high above France that the intense cold deprived them of power to descend. When the "Zenith" came down they were found frozen to death in the basket. During the siege of Paris two balloons with escaping passengers drifted off to sea never to be heard of and in 1888 the corpse of Simmons who had ascended from Olympia came to earth near Malden.

Hiram Maxim a few years later spent $100,000 on two immense heavier-than-air flying machines the last —which weighed 8,000 pounds making a false start in July 1894 when the machine ran off the guard rails. Maxim gave up in disgust and turned to other problems.

Then in 1896 Otto Lilienthal of Berlin after a quarter century of tedious experimenting brought forth a double decked aeroplane in which he soared through the air at race-horse speed sixty or seventy feet above ground. Prof Robert W Wood of Johns Hopkins University went over to Berlin to test the apparatus and made the snapshot used herewith. A few days after this picture was taken Lilienthal fell from the same apparatus in the same spot and was picked up dead. Shortly afterward the experimenter Pilcher who had been continuing Lilienthal's methods in England met death in much the same way.

The same year S A Andree of Sweden accompanied by Nils Strindberg and Dr Ekholm two other adventurous Swedes started in his balloon from Spitzbergen in search of the North Pole and no trace of them has since been found.

In 1896 the hope of science was renewed by Langley our great astronomer and physicist who after a decade of the most careful experimentation flew a steam aerodrome three quarters of a mile over the Potomac. This not being large enough to carry its engineer the army allowed the inventor $[illegible]0,000 with which to perfect a man-carrying machine. The quarter-size model of the latter also sailed successfully over the Potomac in the face of the wind but when the full-size aerodrome was about to leave the launching track a defective part of the launching apparatus caught it and precipitated it engineer and all into the water. Although the big aerodrome never had a chance to try its wings the press so ridiculed the enterprise that appropriation for repair was refused and Langley despite his other great contributions to science died a disappointed man.

Count Zeppelin's new craft [illegible]41 feet long was making a long official test splendidly in August 1908 when the balloon caught fire.

And finally comes Orville Wright riding to victory in his heavier-than-air machine which is scarcely inside the goal when it dumps him out with a broken thigh and several fractured ribs and with him spills to earth young Lieut Selfridge whom soldiers solemnly bear on a litter to the military hospital where occurs three hours later one of the more recent of the many fatalities of our chronicle of tragedy.

The two fatal accidents which have occurred in France with the motor-driven aeroplane within the last few weeks have further dampened the enthusiasm of many would-be aviators. The first of these which happened on September 7th resulted in the death almost instantly of Lefebvre who was one of the newest and probably the most daring of all the French aviators. The second one which occurred only last week (September 22nd) snuffed out the life of Capt Ferber who was probably the best known theorist and practician in the art of aviation in France. Both of these accidents occurred while the men were trying out new machines. In the case of Lefebvre he was making his first flight with a new Wright biplane. The machine rose in the air without difficulty and flew for some distance in a straight line. Lefebvre made an excellent turn and was flying back again in a straight line when suddenly the machine dived to the ground striking its head on with terrific force. The motor fell upon the aviator who was crushed and had his skull fractured.

Capt Ferber on the other hand was experimenting with a new Voisin aeroplane. He had flown half a mile at a height of about [illegible] feet and was making a turn when the machine tipped a great deal and also dropped on the turn so that the end of the lower plane struck the ground. The machine reared on its nose and Ferber was thrown to the ground the motor falling upon him. He managed to extricate himself and was able to walk to the grandstand with the aid of some spectators. He said that he had flown too low and that he had been bothered by the wind in making the turn. He was not seriously injured to all appearances but in a few minutes a hemorrhage set in and he died before a doctor arrived. The machine was badly damaged and it was a wonder that the aviator was not instantly killed. Capt Ferber probably did more than any other man to bring the art of aviation to its present advanced point. He was much of a theorist and only lately he published an article in which he deplored the weight of the present-day machines and gave it as his opinion that no progress had been made in perfecting these during the past six months. The fatal accident which occurred at Boulogne was preceded by another bad smash less than a week before. In this instance the machine broke a rudder and one of the planes.

Rate of Helium Production

In a recent issue of Nature Mr R J Strutt contributes a communication on "Rate of Helium Production from the Complete Series of Uranium Products."

A knowledge of this constant is essential to the estimation of the ages of minerals from their helium content. In a paper published in Proc Roy Soc July 28th 1908 Mr Strutt gives the age of some minerals provisionally on the assumption that the rate was 9.13 × 10[illegible] cubic centimeters per gramme U_3O_8 per annum. This rate was calculated from Rutherford's indirect data. It has received much support from Sir J Dewar's determination of the rate of production by radium with its immediate products. Mr Strutt is now in a position to confirm it further by an experiment on the rate of growth of helium in a solution of pitchblende. He speaks of a solution but it has been found impracticable to take up all the constituents by one solvent. Two solutions were necessary.

The pitchblende solutions contained 11 [illegible] grammes of U_3O_8 and yielded in sixty-one days a quantity of helium which was measured as 2 [illegible] 10[illegible] cubic centimeters in the capillary of a McLeod gage. This gives the rate as 10.4 [illegible] 10[illegible] cubic centimeters per gramme U_3O_8 per annum. No stress can be laid on the close agreement with Rutherford's estimate in view of the very small gas volume measured. The experiment proves however that that estimate is of the right order of magnitude. Larger scale experiments are in progress and these in connection with similar experiments on thorianite will it is hoped enable data on the quantity of helium in minerals to be translated into estimates of time with full confidence.

Railway Tree Planting

The Pennsylvania Railway is planning to set out more than 1,000,000 trees. This will make a total of [illegible]430,000 trees planted in the last three years to provide for some of the company's future requirements in timber and sleepers. This constitutes the largest forestry plan yet undertaken by any private corporation. Heretofore the company's forestry operations have been confined to a limited area between Philadelphia and Altoona. This year however [illegible] 000 trees are being set out on tracts of land near Metuchen and New Brunswick N J. In addition there are to be planted within the next month 207,000 trees near Conewago Pa, 186,000 in the vicinity of Van Dyke, [illegible] at Lewistown Junction, 7,000 at Pomeroy, and [illegible] at Denholm.

THE HEAVENS IN OCTOBER.

BY HENRY NORRIS RUSSELL, PH.D.

WHAT astronomical problem has been so much before the public during the past month as this How can a man determine when he is at the north pole?

As many incomplete or misleading answers have come to the writer's notice it may be appropriate to give a brief review of the matter here

An observer standing at the earth's north pole would have the celestial pole (not the pole star which is 1¼ deg distant) in his zenith The stars during the long night would appear to circle round the sky from left to right always at the same altitude above the horizon the sun to circle similarly, rising slowly from the horizon to its maximum altitude of 23½ deg between March and June, and sinking again until its disappearance in September The change in the sun's altitude from day to day (which equals that in its declination) is accurately known, and can be taken from a small and easily portable table

For an observer near but not at the pole, the celestial pole would be displaced from his zenith—toward that point of the horizon where the earth's pole lay—by one degree for every 60 nautical miles of distance The stars—or the sun after allowance is made for its change of declination—would still appear to circle round the heavens but would be lowest when due north—i e, toward the pole—and highest when due south The whole change in their altitude would equal twice the observer's distance from the pole For latitudes up to 80 deg or more (that is more than five or six hundred miles from the pole) this change in altitude is very conspicuous and observations can easily be made when the sun is highest (at local noon) in the manner familiar to mariners But for an observer within a few miles of the pole these changes in altitude would no longer be perceptible to the eye and it would not be obvious in which direction the pole really was To make quite sure it would be necessary to observe the sun's altitude at intervals during the day and also its compass bearing (The compass of course which points toward the earth's magnetic pole 2 000 miles away would be as good a guide there as here but of no service at all in finding the geographical pole) It would then be necessary to march toward that compass bearing in which the sun had the lowest altitude (corrected of course for changes in declination) The distance to the pole in sea miles would be half the difference of the greatest and least altitude in minutes of arc, so that it would then be easy to advance to the right spot—in theory at least'

This discussion tacitly assumes that the observer is on firm land On the drifting polar ice the change in his position during the day would complicate matters. But by making observations for a second day the amount and direction of the drift could be determined for the sun's altitude (still corrected for changes of declination) would be greater in the direction of the drift and less in the opposite direction than on the previous day by the amount of the drift The explorer would then have all the information necessary for his purpose

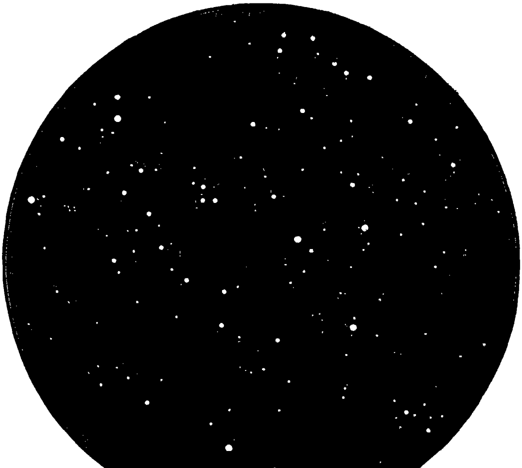
One other point may be mentioned The sun's altitude must of course always be corrected for refraction in the usual way But since the sun's altitude is practically the same all day long the refraction will be constant (except changes due to weather conditions which would probably be very small) The observer's position and drift which are determined from differences of the observed altitudes will therefore be practically independent of the refraction corrections, and also of any "constant errors" of the instrument.

If the conditions of observation were as good as regards temperature and comfort as lower latitudes, an observer of moderate capacity, with portable instruments (sextant, artificial horizon, and chronometer) should be able from two days' observations to find both his position and rate of drift with an uncertainty of only a few hundred feet. Under the actual conditions at the north pole, everything would depend on the experience and skill of the observer, but in any case, he could fix his position with an error which would be quite imperceptible on even the largest-scale maps of the polar regions.

THE HEAVENS

Our map shows the aspect of the evening skies and shows, too, at a glance how dull the southern and eastern skies would be were not Mars and Saturn there to brighten them

The most prominent constellation there is Pegasus, which lies high up south and east of the zenith It may be instantly recognized by the Great Square—about 15 deg on a side, composed of second-magnitude stars, and standing decidedly alone—which is one of the principal landmarks of the sky for the beginner, as it has no counterpart in the heavens. One of its four corners now belongs to Andromeda, but it was once grouped with the other three and evidence of this still remains, for the letter Delta, which it bore as a member of the constellation, is now lacking from the list of the stars of Pegasus The rest of the constellation, extending westward from the Great Square, contains some remarkable double stars (observable only with great telescopes) but nothing to detain us. Our initial letter shows how this constellation, large as it is, is supposed to represent but a part of the winged steed of classic mythology Any actual resemblance would indeed be difficult to trace.



At 11 o'clock Sept. 6.
At 10½ o'clock Sept. 14.
At 10 o'clock. Sept. 21

At 9½ o'clock September 29.

At 9 o'clock Oct. 7
At 8½ o'clock Oct. 15.
At 8 o'clock: Oct. 22.

NIGHT SKY: SEPTEMBER AND OCTOBER

The western edge of the square continued far southward points out the isolated bright star Fomalhaut. The remaining stars of the Southern Fish, though too faint to be shown on the map, are easily visible on a clear night, forming a horizontal line just below the bright one

The equally lonely star some distance east of Fomalhaut is Beta Ceti The rest of the constellation follows this to the eastward. First comes a quadrilateral of which the southernmost star τ is one of our nearest neighbors. Then comes the notable variable Mira—also not far from us in space, and now brightening up and visible to the naked eye, and lastly a group, only the brightest two of which appear on the map. The whole constellation extends over more than 40 deg. and is one of the largest, though not the most conspicuous, in the sky. Above these constellations are the dullest of the zodiacal ones—Capricornus, Aquarius, and Pisces. The second of these, however, now contains the splendid Mars, and the last the less brilliant but still conspicuous Saturn, which both far outshine any stars within a long distance.

The line of stars running to the left from Pegasus, beginning at the northeast corner of the great square, contains the principal stars of Andromeda. Above the middle one of the three, near the second of two small stars, is the Great Nebula, the brightest in the heavens, concerning whose constellation and the problems which it still presents, we spoke a few months ago.

Below this is the inconspicuous but ancient group of Triangulum, and the smaller and brighter one of Aries. The Pleiades are visible north of east, and Aldebaran is just rising

Auriga in the northeast is a little higher up Above it, in the Milky Way, we come in succession to Perseus, Cassiopeia, and Cepheus; then passing the zenith, to Cygnus, Aquila, and Sagittarius (just setting) Ophiuchus and Serpens are also disappearing, due west. A little to the right is the Northern Crown, with the "keystone" of Hercules above it, and the steel blue Vega still higher The Great Bear swings low on the northern horizon, and the Little Bear, enfolded by the Dragon, is higher up

THE PLANETS

Mercury is evening star until the 12th, when he passes on this side of the sun and becomes a morning star He reaches his greatest elongation west of the sun on the 27th, about which date he rises a little before 5 A M, and is easily visible before day break being situated in Virgo a few degrees above the bright star Spica, which however is not as bright as he is

Venus is evening star, and is very bright, but not very conspicuous because she is so far south. During the month she passes from Libra through Scorpio into Sagittarius, and at its end she is 26 deg south of the celestial equator In one latitude she sets a little after 7 P M but for observers in the southern hemisphere she remains in sight three hours longer, and is remarkably prominent

Mars is on the borders of Aquarius and Pisces, rising before sunset, and visible almost the whole night. He moves westward among the stars, ever slower and slower, until the 26th, when he begins the eastward march, which will take him over more than a whole round of the zodiac before another opposition

Jupiter is morning star in Virgo, rising about 5 15 A M. on the 1st, and 3 40 on the 31st, that is, about an hour earlier than Mercury at the time the latter is best seen

Saturn is in opposition on the 18th, and is well observable all through the month. His wings are by this time pretty widely opened out, and he is a very beautiful telescopic object.

Uranus is in quadrature, east of the sun, on the 10th, and south at 6 P. M. Neptune, in almost the opposite quarter of the sky, is in quadrature, west of the sun, on the 15th, and crosses the meridian at 6 A. M.

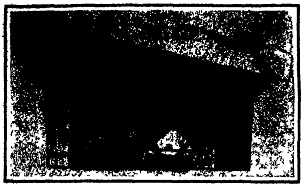
THE MOON

The moon is nearest us on the 27th, and farthest off on the 13th. She is in conjunction with Neptune on the 6th, Jupiter on the 13th, Mercury on the 15th, Venus on the 17th, Uranus on the 21st, Mars on the 26th (early in the morning), and Saturn on the 27th. On the evening of the 20th she occults the bright star Sigma Sagittarii (in the Milk Dipper). As seen from Washington, the star disappears behind the moon's dark limb at 7:01 P. M. and reappears on the bright side exactly at 8 o'clock.

Patent Department

SELF-CLEANING ASHPANS FOR LOCOMOTIVES.

A patent has been recently granted on an ashpan for locomotives, which is provided with novel means for cleaning out the ashes. Our illustration shows a locomotive ashpan fitted with the improved apparatus, and partly broken away to show the details There are, in reality two ashpans one placed before the other and each provided with hoes attached to a piston which may be operated to hoe the ashes out of the pans. The forward pan is provided with two hoes *A* and *B* while the rear pan has but one, *C* Between the two ashpans is a cylinder *D* which is fed with steam through two pipes *E*, that enter at opposite ends of the cylinder The piston in the cylinder is provided with a rod *F* at each end to which the hoes are attached The cylinder *D* is supported between the pans by means of a pair of brackets *G* The forward end of each pan is provided with an outlet normally closed by a damper The rear of each pan is also provided with an opening through which the ashes may be discharged and the rear ends of the hoes *B* and *C* are of such form as to enter and close these openings when they are forced back to the position shown in the illustration When the hoes are moved forward the dampers above referred to are opened by means of forwardly-projecting blades on the hoes *A* and *C* The bottom plate of the forward ashpan is also provided with a discharge opening, which is intermittently opened and closed as the hoe *A* passes over it. The steam pipe *E* leads up to a three-way valve, located at the boiler head in a convenient position for operation by either the engineer or the fireman, who may by this means reciprocate the hoes in the ashpan, and thus cause the discharge of the ashes. The inventor of this improved locomotive ashpan is Mr James S Downing of 185 Cooper Street Atlanta, Ga.

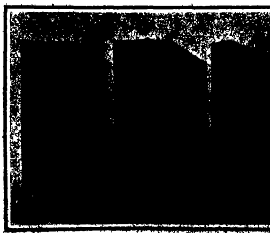


SELF-CLEANING ASHPANS FOR LOCOMOTIVES.

◆

SANITARY REFUSE RECEPTACLE

The ordinary refuse receptacles used in public places are merely open cans in which garbage ashes, or other waste material is placed The fact that these cans are open is a serious objection, because it permits the breeding of germs which may be infectious. Furthermore, it is a temptation to throw lighted matches or cigar or cigarette stumps into the can, and set fire to the contents. To obviate these difficulties, a new type of refuse receptacle has recently been devised which is illustrated in the accompanying engraving It is so arranged that the opening through which the refuse is introduced automatically closes, and in addition to this, the can is provided with a receiver for disinfecting material which will keep the contents in as nearly a sanitary condition as possible Fig. 1 shows the receptacle closed The top or lid of the receptacle may be swung open, as indicated in Fig 2, to permit of dumping the contents of the can The cup of disinfecting material will be observed at the center of this lid. Fig 3 shows the receptacle, with the inlet door open to permit of introducing refuse A spring is attached to the door at the inside, and serves to draw the door shut as soon as it is released When the top of the can is open, as in Fig 2 the lid is fastened to a catch at the front of the receptacle, and this prevents the inlet door from being swung open while the receptacle is being inverted to remove the contents The inventor of this refuse receptacle is Mr Vincent Azzara, 24 Washington Street, Morristown, N J

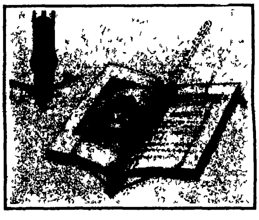


SANITARY REFUSE RECEPTACLE.

◆

CONVENIENT BOOK HOLDER.

Pictured in the accompanying engraving is a holder for magazines and other books designed to hold the book open at any desired point and support the book at each side The cover supports of the holder are adjustable to support the book either fully open or closed, or to support the separated portions of the book in an intermediate position The construction of the device is shown in the fragmentary detail view It consists of a spring clip or gripping device *A*, in the form of a relatively long trough like member of sheet metal which grips the bound edge of the magazine or book Within the clip is a tube *B* which extends beyond the ends of the clip *A* At the upper end of the tube *B* a plug is fitted to snugly engage a rod *C* This rod is provided with a head at the lower end as shown in the detail view which is adapted to contact with the inner end of the plug and prevent the rod from being withdrawn entirely from the tube *B* The rod *C* is bent upon itself into a U form while the outer extremity is turned up to prevent it from digging into the book The cover supports *D* consist of wire wings hinged to the extremities of the tube *B* A wire clip is bent over the hinged ends of the wings and acts as a stop to prevent them from being opened too far In application the clip *A* is passed endwise over the bound edge of the book, and the wings are slightly separated to admit the book between them The book is opened to the desired point, moving the wings outwardly on their hinges, and then the rod *C* is withdrawn from its tube, to the position shown by dotted lines slipped over the open book, and pressed back to its normal position as indicated by full lines In this position the two portions of the book are pressed against the wings and the book may be conveniently held with one hand by grasping the clip *A* which serves as a handle The hinges of the wings are sufficiently stiff to hold them in any position in which they are set Mr Albert F Stone, Jr of Callahan Cal is the inventor of this improved book holder

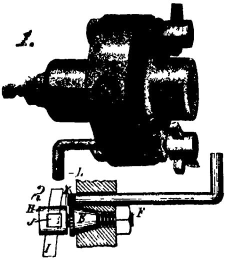


CONVENIENT BOOK HOLDER.

◆

IMPROVED CUTTER HEAD

The cutter head which is illustrated in the accompanying engraving is so designed that the cutting tools may be readily attached or detached at will and may be adjusted as desired without removing them from the cutter head The body of the device which is indicated at *A* consists of a cylindrical barrel having substantially the form of a cup with a flange formed thereon The driving spindle is adapted to enter the barrel, and the cutter head is adjusted thereon by turning the end screw A set screw *C* serves to hold the cutter head to the shaft. A series of conical apertures *D* are formed in the flange They are adapted to receive the split nuts *E* through which the screws *F* are threaded The screws *F* are prevented from turning by means of set screws *G*, which enter keyways therein but by means of nuts on the end of the screws the conical nuts *E* may be snugly seated in the openings *D* The upper end of each screw *F* is provided with a tool holder *H*, adapted to receive a tool or bit *I* which is held in place by means of a set screw *J* Each conical nut is formed with teeth at its outer end adapted to engage a pinion *K* on the end of the key *L* By inserting this key through the apertures from the rear of the cutter the bits may be adjusted at will without removing the cutter head, and then the screws *F* are made fast by tightening up the nuts at the rear The bits may be cut from air-hardening steel of any shape The inventor of this cutter head is Mr John F Stedman of Newberg Ore.

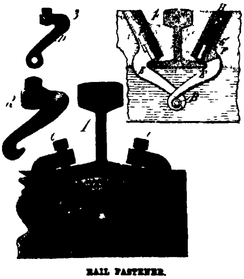


IMPROVED CUTTER HEAD

◆

RAIL FASTENER

The usual method of fastening a rail to the ties has this disadvantage that the base flange of the rail acts like the claws of a hammer under a nail head, to pry the spike out of the wood A better construction would seem to be one in which the axis of the spike lay at right angles to the pull of the rail base With a view to providing such a construction a new type of rail fastener has just been invented which is shown in the accompanying engraving The fasteners may be applied or removed without the use of a hammer and are adjustable to compensate for shrinkage in the ties Fig 1 shows a cross section of a rail fastened to a tie by means of two of the improved rail fasteners *A* The rail fasteners as indicated in Fig 2 are formed with hooks at the lower end adapted to engage a pipe *B*, preferably of cast metal which is fitted into a hole in the tie. The upper end of each fastener is provided with a threaded aperture in which a bolt *C* is fitted. The bolt is adapted to be screwed down on the base flange of the rail Fig 3 shows a slightly modified form of the fastener For street railways a different construction is required as indicated in Fig 4 Here the fasteners *E* are formed with threaded sleeves *F* Screw plugs *G* are adapted to be screwed into the sleeves *F* so as to bring their lower points into contact with the base flange of the rail The rail and fasteners are imbedded in concrete or the street paving material, with only the upper ends of the sleeves exposed It is merely necessary to tighten the screw plugs *G* once in a while by inserting a key wrench in the sockets *H* The inventor of this rail fastener is Mr George Doiffel Fruitvale Cal



RAIL FASTENER.

RECENTLY PATENTED INVENTIONS.

Of General Interest.

SWIVEL AND EXTENSION CONNECTION FOR SUCTION PIPES OR HYDRAULIC DREDGES. J. W. SACKETT, Jacksonville, Fla. This connection is to take the place of the ordinary suction hose and the ball and socket joint now used and arranged to permit the drag to readily accommodate itself to irregularities in the bottom of the waterway to be dredged and to change its relative position with respect to the dredge as the demands of the practical work require and without causing any undue stresses on the suction pipe or the hull of the dredge.

HEAD REST. E. C. LEAHY, Sydney, Nova Scotia, Canada. When used in connection with reclining chairs the invention consists of a head block supported on a universal joint and having head supports with means for locking the joint and supports in adjustable positions, and as a pillow the same general construction is employed, and is supported on the top of a casing vertically adjustable relatively to the casing body. It is for use by barbers, parlor cars, dentists, etc., and as a pillow for campers, patients, etc.

HOLDER FOR ABSORBENT COTTON.—W. J. DURANT, Spencer, Iowa. The invention relates to a holder adapted to receive a roll of cotton, and which is adapted to enable the cotton to be withdrawn as desired, while at the same time it is fully protected from dust and dirt. It is especially useful in the offices of surgeons and pharmacists, and in dispensaries and hospitals.

NON-REFILLABLE BOTTLE.—J. BORNSTEIN, St. John's, Newfoundland. The object here is to provide a bottle arranged to effectively close the bottle when not in use, to allow convenient pouring of the contents of the bottle into a glass or other receptacle and to prevent unauthorized persons from refilling the bottle with spurious goods.

PAVING-BLOCK. D. ATHERTON, Philipsburg, Pa. The aim in this case is to provide a block of which a series can be conveniently assembled to interlock with each other and to form transverse interlocking courses or rows, with a view to prevent transverse shifting of the blocks in the roadway even if the roadway is without curbs.

COLORATION PROCESS. B. D. AVIS, JR., Wallace, W. Va. In the present patent the invention has reference to coloration process, the inventor's more particular purpose being the provision of a simple and inexpensive method of producing iridescent tints and colorations upon glass or upon opaque surfaces requiring comparatively little preparation.

Hardware.

ICE SHAVER.—A. M. PRESTON, Broxton, Ga. The invention consists of a body formed to receive the shaved ice and carrying a shaving blade and a movable member constituting a lid for the body and operable to force the shaved ice from the body, the latter having preferably a plurality of compartments which are simultaneously filled with the ice.

SHOE POLISHER.—F. VALGUIN, San Francisco, Cal. The invention relates particularly to that type of polishers adapted to hold and inclose the polishing fabric. An object is to provide a device which will hold the fabric tightly, and the stronger the pull on the fabric the tighter will the device grip it.

Heating and Lighting.

GAS IGNITING DEVICE. W. GAIX, Schöneberg, near Berlin, Germany. The device consists of an igniter proper, such as a platinum pilule, an electric spark former or an incandescent wire, which is carried directly or through the agency of suitable parts by a compensation rod so that after the gas is ignited the said rod is bent by the heat and moves the igniter out of the zone of hot gases.

Household Utilities.

REFRIGERATOR.—O. M. CAMPBELL, Van Buren, Ark. The purpose here is to provide details of construction of a refrigerator that will render it very convenient, insure proper circulation of cold dry air throughout the interior of the refrigerator, prevent sweaty deposits of moisture on the walls within the refrigerating chamber, and afford perfect drainage for water formed by melting of ice.

RENOVATOR. J. H. BROWN, New York, N. Y. This invention has in view a manually operated device for household use in which the dust and dirt are removed by suction. It consists of two upright wheel-supported frames rigidly connected together at the bottom by a platform and at suitable points thereabove; a receptacle seated on the platform, a nozzle applied to the part to be cleaned, a rotary pump having its inlet connected with the nozzle and discharging into the receptacle, and a driving mechanism for the pump journaled on the frame.

EGG-TESTER. EVELYN LEIBS, Bronxville, N. Y. The invention belongs to that class of testers which consists of a box having openings in the top in which eggs are adapted to be seated, in combination with a mirror in the box under the openings for reflecting such light as passes through the eggs, the same being observable through a sight opening located at a point convenient above the mirror.

Machines and Mechanical Devices.

PULP-REFINING ENGINE.—F. W. QUANTS, Vincennes, Ind. The main object of the inventor is to provide a shell filling which has the corrugated surface necessary for the reduction of the pulp, but which obviates a former objection, in that all of the pulp is forced into repeated and intimate contact with the revolving plug, thereby rendering the product of uniform texture.

ATTACHMENT FOR LINOTYPE-MACHINES.—A. F. WELLING, New York, N. Y. More particularly the invention relates to devices for determining the number of quads to be allowed for a cut, so that the operator will be enabled to assemble the proper number of matrices having intelligible characters to fill the space at one side of the irregular outline of a picture or design and then insert the proper number of quads or blanks to fill the remainder of the line.

NURSERY-CHAIR.—P. S. CHANDLER, Mountpleasant, Tenn. When the chair is set up and the frame is placed in position encircling the chair, the rear ends of the arms are depressed so that the pins engage the enlarged portions of the slots, thus preventing disengagement of the tray from the undercut notches, until the rear ends of the arm are again lifted to disengage the pins.

FRICTION CLUTCH.—M. S. SLAGT and T. J. KELLY, Everett, Wash. One purpose here is to provide details for a clutch, which are simple and quick in operation, not liable to slip and that will positively lock together two parts of a machine they are connected with so that said parts will co-operate or release them instantly when this is essential for the proper operation of the parts connected by the clutch.

GANG EDGER.—D. C. LEONARD, Columbia, S. C. The main object of this improvement is to provide a machine which has movable members constituting part of the frame of the device which can be swung up out of the way to permit easy access to the saws and thereby enable the operator to file them while they are on the arbor.

CALCULATING MACHINE.—C. L. NELSON, Seattle, Wash. This invention relates to improvements in machines of that type in which the keys are operated in accordance with the number to be listed, and more particularly to that type disclosed in a previous patent granted to Mr. Nelson, although various features of the present invention might be employed in other calculating machines than that shown in said patent.

PAPER-CUTTING MACHINE.—G. M. FARNHAM, South Brewer, Me. This invention refers to certain improvements in machines for cutting paper into diagonal strips, and more particularly to that type of machine in which there is employed a cutter disposed at an angle to the roll of paper to be cut and adjustable to vary the angle at will.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Legal Notices

60 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &C.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

Branch Office, 625 F St., Washington, D. C.

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending September 14, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Adhesive fluids, device for supplying, Windle & Ollerenshaw	[illegible]
Adjustable trap, J. H. Brady	[illegible]
Air-brake mechanism, supplemental, A. Dean	[illegible]
Air compressor governor, Kloer & Leowel	[illegible]
Alarm or time check, R. Turek	[illegible]
Album, post card, H. F. Morris	[illegible]
Alkali chlorids, apparatus for the electrolysis of, J. Billiter	[illegible]
Amusement device, Liebling & Schmidt	[illegible]
Amusement device, M. A. Sharples	[illegible]
Armature, knockdown, E. W. [illegible]	[illegible]
Armatures of dynamo electric machines, winding for, R. G. [illegible]	[illegible]
Attaching device, D. Hoyt	[illegible]
Auger, post hole, H. B. West	[illegible]
Automobiles and other machinery, transmission gear for, L. T. Rhoades	934,016
Automobiles, suspension spring system for, O. A. Lieb	933,987
Axle connection for vehicles, front, A. J. Goyette	[illegible]
Axle coupling, reversible car, M. Markarian	[illegible]
Axle skeins for vehicles, construction, J. H. Wilcoxon	[illegible]
Bait, artificial fish, N. W. Moran	[illegible]
Bait holder, J. F. Beatty	[illegible]
Barrel, J. W. Desmond	[illegible]
Basins, etc., stopper for wash, G. Meldau	[illegible]
Bearing, foot step ball, M. Gobeke	[illegible]
Bearing for grain drills, etc., Davis & Board	[illegible]
Bearing, roller, L. J. Aldridge	[illegible]
Bed, J. W. Fuller	933,971
Bed rail notching machine, A. McLean	[illegible]
Bedstead, W. Wokurka	[illegible]
Beer pasteurizing and cooling apparatus, W. Wenzel	[illegible]
Bell, signal, M. W. Eden	[illegible]
Belt attachment, Dalmar & Wander	[illegible]
Belt fastener, J. W. Kidwell	[illegible]
Belt tightener, Wallace & Dow	[illegible]
Bicycle spring fork, H. C. Preston, Jr.	934,013
Bilge water discharger, C. A. Curry	[illegible]
Billiard cue, I. A. Gormon	[illegible]
Billiard cue tip, I. A. Gormon	[illegible]
Block forming machine, C. R. Walter	934,112
Block machine, W. L. Keller	[illegible]
Boat, F. M. Thompson	[illegible]
Boat and vessel, P. Igais	[illegible]
Boiler cleaner and feed water heater, A. N. Jones	934,314
Boiler furnace, locomotive, F. F. Gaines	934,157
Boiler hanger, C. E. Lingenfelter	[illegible]
Boilers, system of washing and filling locomotive, W. White	[illegible]
Book, blank, scrap and similar, B. F. Hoberg	934,311
Book, loose leaf, T. C. Bruhn	[illegible]
Book rest, D. Duff	934,148
Boot or shoe, C. Pease	[illegible]
Bottle, S. Rolfsen-Schmidt, 934,[illegible]	934,259
Bottle cap, G. E. Stahl	933,795
Bottle cap lifter and cigar cutter, E. C. Hunt	[illegible]
Bottle holder, J. F. Parker	934,344
Bottle mat, milk, C. A. Steinman	934,230
Bottles, jars, and the like receptacles, closure for, A. F. White	[illegible]
Bow separator, C. H. Titrbener	[illegible]
Bracket, F. J. Moran	934,414
Brake. See Load brake	
Brake system, fluid pressure, W. H. Sauvage	934,019
Bridle irons or stirrup or joist hangers, machine for shaping, W. Hansen	934,168
Brooder, A. Noble	934,206
Brush, bottle and like cleaning, G. A. & C. C. Farrar	934,058
Brush hook and ax combined, C. R. Olson	934,008
Bucket for concrete building material, N. C. Newerf	934,082
Buckle, cross line, A. F. Carlson	933,745
Burglar alarm, electric, M. Trautmann	934,108
Bust reducing attachment, J. M. Bodendick	933,730
Calcium silicid, producing, Wilson & Haff	934,379
Calculating machines, setting device for, J. Gruber	934,401
Calk, removable, G. S. Meyer	934,197
Calks on horseshoes, machine for forming and sharpening, Snover & Palmer	933,996
Camera mechanism, photographic, W. Verbeck	933,891
Can closing machine, C. M. Symonds	934,371
Can covers, apparatus for cleansing, sterilizing and drying milk, C. H. Hood	934,404
Can feeding and righting machine, M. D. Blakeslee	934,184
Can heading machine, single, Adriance & Calleson	933,873
Candle gathering implement, C. R. Manbeck	934,198
Candy making machine, Hudson & Camp	933,967
Candy mold, H. J. Hedrich	934,310
Car, G. G. Fryer	[illegible]
Car body, J. M. Hopkins	[illegible]
Car check, railway, J. Keson	933,760
Car coupling, W. L. Wright	933,941
Car coupling, R. B. Chalmers	[illegible]
Car, drop bottom dump, H. C. Brunker	934,279
Car, dumping, A. Becker, 934,267	934,268
Car fender, E. Barrett	[illegible]
Car fender, C. Gardiner	933,973
Car, passenger, Curwen & Smith	934,149
Car, passenger, C. K. Pickles	[illegible]
Car safety stop, W. Gunter	[illegible]
Car seat, H. White	934,121
Car underframe, A. Becker, 934,262,	[illegible]
Cars, drop door fastening for, Furgeson & Wheland	[illegible]
Cars, drop door operating mechanism for hopper bottom, A. Becker	934,269
Carbureter, M. Steel, Jr.	934,367
Cards, electrical pattern for the manufacture of jacquard, P. Weissenborn	[illegible]
Carpet sweeper, G. B. Deacon	[illegible]
Caster attaching bearing box, V. C. Leppert	[illegible]
Caster, furniture, G. E. Neuberth	934,004
Caster leg mount, G. E. Neuberth	934,005
Casting rolls, J. L. Lewis	[illegible]
Casting rolls, mold for, J. L. Lewis	934,410
Cement block, W. L. Keller	[illegible]
Cement blocks, waterproof, J. A. Fincke	934,081
Cement clinker, process and apparatus for making, C. Ellis	934,056
Centrifugal machine, H. Schmitz	[illegible]
Chain tightener, C. H. Peterson	[illegible]
Chain tightener and lock, F. A. Fox	934,154
Chair. See Nursery chair	
Chair, W. M. Clark	[illegible]
Check bit, T. Tippit	[illegible]
Cheese cutter, O. O. Oslas	[illegible]
China, etc., apparatus for casting hollow and other ware of, W. Stubbs	[illegible]
Chlorin, separating and concentrating, Goldschmidt & Spitzer	934,400
Chuck, W. G. Sanborn	[illegible]
Chuck, drill, J. Bradley	[illegible]
Churn, J. T. Armstrong	[illegible]
Churns, lever construction for, R. M. Rowe	[illegible]
Chute, package, Perpignan & Biebelman	[illegible]
Cigar lighter, F. J. Wildemann	934,119
Clamp, G. N. Hall	[illegible]
Cleaning apparatus, F. J. Seeley	[illegible]
Clock, electrically operated, H. Gillette	[illegible]
Clover huller, J. C. Kistler	[illegible]
Clutch driving mechanism, controlling means for electrical, A. F. Stoekel	934,104
Clutch mechanism for automobiles and for other applications, friction, A. [illegible]	[illegible]
Coal washer, F. R. Wilson, Jr.	[illegible]
Coat, G. W. Davis	[illegible]
Cock, quick acting bib, L. J. Sommer, Jr.	[illegible]
Cocks, locking air, J. E. Sheafe	[illegible]
Coffee percolator bag, L. Norwood	[illegible]
Coffee roaster, L. Breyer	[illegible]
Coil winding apparatus, H. R. Smith	[illegible]
Coil winding machine, F. Mueller	[illegible]
Coin drawing apparatus, H. D. Ratliff	[illegible]
Colander, M. A. Ratliff	[illegible]
Column, wooden, C. A. Nickerson	[illegible]
Comb, H. Jennison	[illegible]
Composing machines, means for justifying tabular matter in typographical, [illegible] & Longhurst, [illegible]	[illegible]
Composition of matter, G. W. Boggs	[illegible]
Composition of matter, C. J. & F. G. Martus	[illegible]
Concrete bridge, D. B. Luten	[illegible]
Concrete building and holding mechanism, A. N. Dodd	[illegible]
Concrete chimney construction, G. [illegible]	[illegible]
Concrete-mixers, power charging device for, R. B. Symons	[illegible]
Concrete, reinforced, W. H. White	[illegible]
Concrete structure, reinforced, E. [illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
Corset, C. H. Cooley	[illegible]
Corsets, hip reducing attachment for, J. M. Holmes	[illegible]
[illegible], M. Grady	[illegible]
Coupling, Barsalo & Ferrandi	[illegible]
Coupling, J. L. Walker	[illegible]
Cover retainer, J. M. Brown	[illegible]
Crate, H. D. Gibbs	[illegible]
Crate, J. H. Mahoney	[illegible]
Crate, C. R. Burwell	[illegible]
Crate, folding, R. H. Goddard	[illegible]
Crate, shipping, J. H. Nash	[illegible]
Cream ripener, T. L. Valerius	[illegible]
Cross head, A. Dubuque	[illegible]
Cuff holder, W. J. Noels	[illegible]
Cultivator, H. Tripp	[illegible]
Cultivator, cotton, J. J. Green	[illegible]
Cultivator, gravity hand, J. E. Hosmer	[illegible]
Current transformer regulator, alternating, A. C. Lanier	[illegible]
Currents machinery, safety device for polyphase, J. M. S. [illegible]	[illegible]
Curtain frame, W. [illegible]	[illegible]
Cut off, automatic, C. M. Brown	[illegible]
Cycles and like vehicles, toe clip for the pedals of, H. Frankenburg	[illegible]
Cylinder head, F. L. Sessions	[illegible]
Cylinder printing apparatus, Nahm & O'Brien	[illegible]
Decoy, Oliver & Westcott	[illegible]
Delivery apparatus, H. B. Murray, Jr.	[illegible]
Deposit and collection receptacle, C. F. Bryant	[illegible]
Die stock, R. H. Burke	[illegible]
Dipping tank, Viktor & John	[illegible]
Dish washing machine, A. L. Pearce	[illegible]
Dispensing receptacle, K. C. Jopling	[illegible]
Display case and valise, combined, C. Billburg	[illegible]
Display rack, J. [illegible]	[illegible]
Door adjusting device, A. Hollmann	[illegible]
Door check and closer, G. [illegible]	[illegible]
Door opening device, A. B. Flowers	[illegible]
Door stop, S. P. Creswell	[illegible]
Dough dividing machine, T. W. Kaiser	[illegible]
Draw bar carrier, C. H. Tomlinson	[illegible]
Drawer pull, C. B. Adams	[illegible]
Dress suit cases, traveling bags, and the like, handle cap for, F. Waldschmidt, Jr.	[illegible]
Drill steel coupling, C. C. Hansen	[illegible]
Drills or other apparatus, carriage for portable pneumatic, R. H. Robinson	934,418
Driving mechanism, N. Smolensky	[illegible]
Dropper. See Trellis wire dropper	
Dye, azo, Jansen & Neelmeier, 933,941,	[illegible]
Dye, brown sulfur, Oley & Dieterle	[illegible]
Dye, olive sulfur, Oley & Dieterle	934,306
Eaves trough strainers or protectors, fastener for, W. Feyler	[illegible]
Electric apparatus, ventilating plate and spacing block for, J. A. Baird	933,737
Electric furnace, T. F. Baily	[illegible]
Electric heater, C. R. Johnson	[illegible]
Electric light cluster fixture, J. H. Caldwell	[illegible]
Electric machine, dynamo, W. D. Pomeroy	934,210
Electric machine, dynamo, A. H. Wouters	[illegible]
Electric machine, dynamo, L. J. Hunt	[illegible]
Electric signal, W. K. Howe	[illegible]
Electrical apparatus, ventilating plate and spacer for, H. D. Summers	934,369
Electrical energy on any circuit, arrangement for indicating and recording permanently the maximum demand for, Lackie & Steele	[illegible]
Electrical switch, F. H. [illegible]	[illegible]
Elevator, D. Corcoran	934,141
Engines, adjustable crank for internal combustion, C. J. Gotti	934,164
Engines, gearing for traction, A. W. Aitken	[illegible]
Engraving machine, A. Rostad	[illegible]
Envelop opener, W. L. Barber	[illegible]
Excavator, hydraulic, C. B. Askew	[illegible]
Explosive, O. F. von Schroetter	[illegible]
Eyeglasses, W. H. Weaser	934,118
Eyeglasses, connecting guard for, M. B. Kosman	[illegible]
Eyeleting machine, G. Goddu	[illegible]
Fabrics, apparatus for removing lye from, O. Venter	934,110
Fastener, K. Green	[illegible]
Fastener for hinged closures, adjustable, J. Jenks	934,180

The
ONOTO
FOUNTAIN PEN
COSTS YOU
NOTHING—
unless you find it is and does *all* we claim!

This is what we claim:—

1 Fills and cleans itself in 5 seconds.
2 Cannot leak even when carried point downward
3 SELF-REGULATING ink flow Writes just as fast or slow as you wish
4 INSTANTANEOUS ink flow Writes at the FIRST stroke
5 CONTINUOUS ink flow Never MISSES a stroke
6 EXACTLY EVEN ink flow Never blots, splatters nor floods
7 14 K Gold Iridium tipped points Never catch nor scratch and last for years
8 Double ink feed—one above and one below the nib (The secret of Features 3 4 and 5)
9 Barrel and cap made of finest quality polished black Vulcanite
10 No dropper, clip or special ink necessary
11 A point, a size and a price for every Hand, every Purpose and every Pocketbook
12 Sold on an UNCONDITIONAL Guarantee of absolute Satisfaction—OR MONEY BACK!

No other Fountain Pen, at ANY price, has ALL these 12 features. Few have even one of them. Yet the Onoto COSTS YOU NO MORE than the old-fashioned finger-besmearing leaky Dropper-Fillers or the new-fangled impractical Rubber Sack and Pump-filling kinds!

Simply see and *try* the Onoto This is all we ask And it's all we *need* to ask Because Seeing means Trying, Trying means Buying and Buying means guaranteed Satisfaction

Four Sizes—$2 50 $3 $4 and $5 15 different style points in each size

Look for the word ONOTO before you buy It appears on the barrel of every genuine ONOTO—your Guide and our Guarantee

Sold everywhere, by the leading Stationery Department and Drug stores If no local dealer is willing to supply you write to us for Onoto Catalog 8 names of the nearest Onoto dealers and FREE Onoto Score Pads for "Bridge" or "Five Hundred" Please name your favorite local dealer

Three New Interesting Books

The Scientific American Boy at School

By A. RUSSELL BOND

12mo. 320 Pages. 300 Illustrations.
Price $2.00 postpaid.

THIS book is a sequel to "The Scientific American Boy," many thousand copies of which have been sold, and has proven very popular with the boys. The main object of the book is to instruct how to build various devices and apparatus, particularly for outdoor use. The construction of the apparatus is fully described and the instructions are interwoven in a story, a feature which has assisted in making the "Scientific American Boy" so popular and interesting to the boy.

It takes up the story of "Bill" and several of his companions at boarding school. They form a mysterious Egyptian society whose object is to emulate the resourcefulness of the ancients. Their Chief Astrologer and Priest of the Sacred Scarabeus is gifted with unusual powers, but his magic is explained so that others can copy it. Under the directions of the Chief Engineer dams, bridges and canal locks are constructed. The Chief Admiral and Naval Constructor builds many types of boats, some of which are entirely new. The Chief Craftsman and the Chief Artist also have their parts in the work done by the Society, over which Pharaoh and his Grand Vizier have charge. Following is a list of the chapters:

Chapter I, Initiation; Chapter II, Building a Dam; Chapter III, The Skiff; Chapter IV, The Lake House; Chapter V, A Midnight Surprise; Chapter VI, The Modern Order of Ancient Engineers; Chapter VII, A "Pedal Paddle Boat"; Chapter VIII, Surveying; Chapter IX, Sounding the Lake; Chapter X, Signaling Systems; Chapter XI, The Howe Truss Bridge; Chapter XII, The Seismograph; Chapter XIII, The Canal Lock; Chapter XIV, Hunting with a Camera; Chapter XV, The Gliding Machine; Chapter XVI, Camping Ideas; Chapter XVII, The Haunted House; Chapter XVIII, Sun Dials and Clepsydras; Chapter XIX, The Fish Tail Boat; Chapter XX, Type Photography; Chapter XXI, Water Tights and Current Sailing; Chapter XXII, The Wooden Canoe; Chapter XXIII, The Bicycle Sleigh; Chapter XXIV, Magic; Chapter XXV, the Sailboat; Chapter XXVI, Water Sports, and Chapter XXVII, A Geyser Fountain.

Handy Man's Workshop and Laboratory

Compiled and Edited by A. RUSSELL BOND

12mo. 400 Pages. 350 Illustrations.
Price $1.50 postpaid.

EVERY practical mechanic, whether amateur or professional, has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity. The resourceful man who has met an issue of this sort successfully seldom, if ever, is adverse to making public his methods of procedure. After all he has little to gain by keeping the matter to himself and appreciating the advice of other practical men in the same line of work he is only too glad to contribute his own suggestions to the general fund of information.

About a year ago it was decided to open a department in the Scientific American devoted to the interests of the handy man. There was an almost immediate response. Hundreds of valuable suggestions poured in from every part of this country and from abroad as well. Not only amateur mechanics but professional men as well were eager to recount their experiences in emergencies and offer useful bits of information, ingenious ideas, wrinkles or "kinks," as they are called. Aside from these many valuable contributions came from men in other walks of life, resourceful men, who showed their aptness at doing things about the house, in the garden, on the farm. The electrician and the man in the physics and chemical laboratory furnished another tributary to the flood of ideas. Automobiles, motor cycles, motor boats and the like frequently call for a display of ingenuity among a class of men who otherwise would never touch a tool. These also contributed a large share of suggestions that poured in upon us. It was apparent from the outset that the Handy Man's Workshop Department in the Scientific American would be utterly inadequate for so large a volume of material, but rather than reject any really useful ideas for lack of space we have collected the worthier suggestions, which we present in the present volume. They have all been classified and arranged in eight chapters, under the following headings:

I, Fitting up a Workshop; II, Shop Kinks; III, Soldering of Metals; IV, The Handy Man in the Factory; V, The Handy Man's Experimental Laboratory; VI, The Handy Man's Electrical Laboratory; VII, The Handy Man About the House; VIII, The Handy Sportsman.

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON
Assistant Secretary Concrete Association of America

12mo. 200 Pages. 150 Illustrations.
Price $1.50 postpaid.

THIS work should appeal strongly to all those interested in ornamental concrete, as the author has taken up and explained in detail in a most practical manner the various methods of casting concrete in ornamental shapes. The titles of the thirteen chapters which this book contains will give a general idea of the broad character of the work. They are entitled:

I, Making Wire Forms and Frames; II, Covering the Wire Frames and Modeling the Cement Mortar into Form; III, Plaster Molds for Simple Forms; IV, Plaster Molds for Objects Having Curved Outlines; V, Combination of Casting and Modeling—An Egyptian Vase; VI, Glue Molds; VII, Colored Cements and Methods Used for Producing Designs with Same; VIII, Selection of Aggregates; IX, Wooden Molds—Ornamental Flower Pots Modeled by Hand and Inlaid With Colored Tile; X, Concrete Pedestals; XI, Concrete Benches; XII, Concrete Fences; XIII, Miscellaneous, Including Tools, Waterproofing and Reinforcing.

The first two chapters explain a most unique and original method of working pottery which has been developed by the author. The chapter on color work alone is worth many times the cost of the book inasmuch as there is little known on this subject, and there is a large and growing demand for this class of work. The author has taken for granted that the reader knows nothing whatever about the material and has explained each progressive step in the various operations throughout in detail. These directions have been supplemented with half tones and line illustrations which are so clear that no one can misunderstand them. The amateur craftsman who has been working in clay will especially appreciate the adaptability of concrete for pottery work, inasmuch as it is a cold process throughout, thus doing away with the necessity of kiln firing, which is necessary with the former material. The book is well gotten up, and is printed on heavy glazed paper and abounds in handsome illustrations throughout, which clearly show the unlimited possibilities of ornamentation in concrete.

Send your orders now, and a copy of the book desired will be mailed on the day of publication.

MUNN & CO., Inc., Publishers, 361 Broadway, New York

Your best negatives deserve, and your poorer negatives need:—

VELOX

Velox is the only paper that is made with sole reference to the requirements of the amateur. The best developers and finishers of amateur work use Velox exclusively because it is the only paper that works properly with negatives made under the harsh conditions of lighting that the amateur almost invariably encounters.

Don't permit anybody to insult your negatives with an inferior substitute.

If your developer and finisher doesn't use Velox, write us; we will tell you of one who does

Government Homesteads

Over one and one half million acres of land open for settlement in Cheyenne River and Standing Rock Indian Reservations, October 4th to 23rd.

Registration at Pierre and Aberdeen, S. D.

Direct route to registration points is the Chicago & North Western Ry.
Special low homeseekers' round trip rates.

This land is well watered by the Cannon Ball, Grand, Moreau and Cheyenne Rivers and their tributaries. The soil is a light loam, fertile and makes a good grain producing land. The land must be lived on and improved. A low valuation of from 50 cents to $6.00 per acre has been placed on the land by the Government, arranged in easy annual payments covering a period of five years.

The Oil That Turns Minutes To Miles

Vacuum MOBILOIL relieves your automobile of wear and friction and leaves it free to wrestle with the minutes and the miles. It makes perfect lubrication a scientific certainty and saves paying for experiments and accidents, disguised as repairs.

VACUUM MOBILOIL

is made in six different grades for various kinds of automobiles. One of these grades is the one oil the label of which guarantees it to be exactly suited to the requirements of your car.

Do not experiment. Write for free booklet, listing every automobile made and showing grade of MOBILOIL necessary for its perfect lubrication. Also contains track records to date and other facts of vital interest to motorists.

MOBILOIL in barrels, and in cans with patent pouring spout, is sold by dealers everywhere. Manufactured by

VACUUM OIL CO., Rochester N Y

Curtiss Motorcycles

WORLD'S RECORD MOTORCYCLES

Low truss frame. Roller bearing engine. Light weight, great power. Write for catalog and booklet "Achievements."

THE HERRING-CURTISS CO., Hammondsport, N. Y.

GEER MOTORCYCLES

[illegible]

We have the largest line of new and used Motorcycles in the country at the lowest prices. Every machine guaranteed. Repairs a Specialty. Motors and Castings for Air Ships. Motors for railway velocipedes. Send for Catalog.

Perfect One Horse-Power Engine At Last

It is the strongest and best small engine you ever saw. The work it will do will delight you—so easy to operate and to shift from one job to another. **The Jack Junior, a One Horse-power Marvel,** has horizontal evaporating tank which takes the place of water jacket and does away with the large water cooling tank required on other engines. Jack Junior is made of the highest grade materials with all working parts expertly machine finished. Four cycle, water cooled, make and break electric ignition. Uses gasoline or kerosene at less than 1 cent per hour. Jack Junior will pump water, run cream separator, milking machine, churn, washing machine, grindstone, small air compressor, lathe or band saw, small corn sheller or ice cream freezer—in fact, any machine not requiring over one horse-power. Jack Junior is mounted on wood base, complete with battery, all ready to run.

Gas Engines from 1 to 50 H.-P., Pumping Engines, Pumps, Pump Jacks, Electric Lighting outfits, Belting and Supplies.

The Gun That Shoots. FOR MEN AND BOYS

Sends a shot entirely through one-half inch pine and tears. Uses compressed air—no springs—same as used by powerful rock drills, air brakes, etc. Many times more powerful than any other Air Rifle. Force of shot under control. Accurate. One may shoot 10 sparrows in one day. Shot fired by this gun at iron target at 50 feet. Another shot [illegible] Others shoot rabbits and squirrels. Practical gun for all small game. Discharge does not scare game. Can be used where cartridge guns cannot, indoors or out. Ammunition costs 10c or less for 1,000 shots. Sold by dealers and jobbers. If your dealer does not sell it, write us. There is no substitute or "just as good." Sent prepaid in U. S. and parcels post countries upon receipt of $[illegible]. Descriptive circulars upon request.

[illegible] St. Louis, Mo.

For Everybody

wishing to bore a hole in steel, iron or wood. We make drills in 7 sizes. Our large size will drill a 7/8 inch hole in steel. Our Electric Midget weighs only 4 pounds, and will drill in steel up to 3-16 inch. Great for manual training schools. We also make electric driven grinders. Let us send one on 10 days' trial. Send for catalogue.

THE CINCINNATI ELECTRIC TOOL CO.

PHILADELPHIA, THE DELAWARE RIVER, AND JOHN FITCH.

The widespread interest in the early history of the steamboat which has been aroused by the present splendid tribute to the work of Robert Fulton on the Hudson River, has served to bring into public notice several too-long neglected inventors, prominent among whom is John Fitch With the exception of a small craft which he tried on the old Collect Pond in this city, the whole of the experimental work of this worthy man was done in Philadelphia and on the Delaware River

We are free to confess that although we have always associated the name of Fitch with the development of the steamboat, it was not until we began to make a more thorough search of the history of the early inventors that we realized how important a part John Fitch had played in that period, how meritorious was his work, and how practical the degree of success which he attained

It has been freely admitted that the present festival commemorates merely the inauguration of successful steamboat navigation on the Hudson River, and that the question as to who produced the first practical passenger-carrying steamboat is still an open one Therefore we suggest, in view of the fact that during three months of the summer and autumn of the year 1790 John Fitch was operating a passenger carrying steamboat on the Delaware, which sailed according to a fixed schedule and was advertised in the daily papers of that day that it is incumbent on the city of Philadelphia to do justice to the memory of its too-long neglected citizen

The story of his life and his heroic struggle to design a successful steamboat as written by his own hand reposes at present in the Philadelphia Library to whose care it was committed by Fitch shortly before his tragic death This unique autobiography consists of five old ciphering books, dog-eared and thumbworn whose five hundred pages, covered with the characteristic writing of the author contain several drawings showing the various steps by which he developed the jet condenser which played so important a part in driving his successful passenger steamboat of 1790 Regarding the criticism that his method of propulsion by means of a set of reciprocating paddles, arranged in a frame at the stern of the boat, was cumbersome and awkward we would point out that, before making use of vertical paddles, Fitch investigated the rotating paddle wheel and rejected it on the ground that much of the power of the engine was uselessly expended because of the obliquity of the paddles in entering and leaving the water, the water being alternately forced down and thrown up, with a proportionate loss of propulsive efficiency On the other hand argues Fitch paddles can be made to enter and leave the water in an approximately vertical position and practically the whole of the power can be used to good effect Now in this Fitch showed his engineering good sense and it was not until over half a century later that the feathering paddle wheel was introduced In this type the floats are hinged at the outer ends of radial arms from a shaft, and by means of an eccentric to which each float is also attached they are made to enter and leave the water in an approximately perpendicular position, a condition which John Fitch secured by his clumsy but effective reciprocating paddle arrangement. That it was efficient is shown by the fact that he attained on a measured mile as testified to by several witnesses of high standing in the community a speed of eight miles an hour, and that he ran his boat regularly between Philadelphia, Trenton, and way points at an average speed of seven miles an hour This, be it remembered, was from two to three miles better than the best speed of the 'Clermont" some twenty years later

The ultimate failure of John Fitch was due to a lack of influential backing and to a combination of unfortunate accidents. During the winter following his successful season of 1790 he was engaged in the construction of a larger and more powerful vessel called the 'Perseverance," which, unfortunately, was torn adrift and wrecked during a heavy storm on the Delaware River Fitch understood full well the value and significance of his work and he also realized that if he failed it was not because of any inherent fallacies in his plans, but merely for lack of influence and the necessary financial support. Pitifully prophetic is the following sentence from the diary of this disappointed inventor, who evidently foresaw at that time his early death "The day will come when some more powerful man will get fame and riches from my invention, but nobody will believe that poor John Fitch can do anything worthy of attention" The remains of Fitch lie in an unmarked grave The scene of his labors is to-day barren of monument or memorial to bear tribute to his remarkable work.

We commend these facts to the consideration of the citizens of Philadelphia and those towns along the Delaware River which were the scene of his early labors and triumphant but short lived success, in the hope that they may see their way to honor the memory and perpetuate the work of Fitch by some such services and permanent memorials as have marked the present Hudson Fulton Celebration

PALESTINE AND SYRIA THE ORIGINAL CEREAL COUNTRIES.

The origin of the cultivation of cereals has seemed lost in the night of time At the beginning of the historical period, the culture of wheat had extended throughout the ancient world It was practised in Egypt 4,000 years before the Christian era, and wheat is one of the five plants included in the annual sowing ceremony which the Chinese Emperor Chin nung instituted 2,900 years before that era. Wheat and barley have also been found, in considerable quantities, in the palafitte or lake dwellings erected on piles in prehistoric times.

Ten years ago the problem of the origin of cereal culture was deemed insoluble, for botanists thought that wheat would never be found growing wild in any part of the world Subsequently, however, much light has been thrown on the question by the theoretical views of Koernicke, who has reorganized the classification of cultivated varieties of wheat, and especially by the diligent historical researches of Aaronsohn

Among the specimens of wild barley (*Hordeum spontaneum*) collected in 1855 by Kotschy, at the foot of Mount Hermon near Damascus, was found a single example of a different grain, the importance of which was ignored at the time Koernicke observed this plant in 1873, but devoted little attention to it until 1889 when he described it under the name *Triticum vulgare* var *dicoccoides* He regarded it as the parent of our cultivated varieties of wheat, and his opinion was adopted by Ascherson and Schweinfurth. But this theory was founded on a single plant, which might well have been a plant of cultivated wheat accidentally mixed with the wild barley, for two other botanists had failed to find additional specimens in the same locality Aaronsohn was equally unsuccessful in 1904, when he went to Mount Hermon in quest of the plant but in 1906 he found the *Triticum dicoccoides* growing abundantly and in a great variety of forms on Mount Hermon up to an altitude of 6,000 feet, and at other points in Syria and Palestine It should be noted that wheat is not cultivated in either of these countries.

The plant is always found associated with wild barley and grains of wheat and barley have always been found together in lake dwellings and Egyptian ruins, so that our ancestors appear to have cultivated the mixture of barley and wheat with which nature provided them The Arabs have only one name for the two wild grains.

In 1907 Aaronsohn found a few rye plants in Syria It is generally supposed that rye is a native of Europe and is, and always has been, unknown in the Orient. In 1908 Aaronsohn found wild barley in the valley of the Dead Sea, and wild wheat (*Triticum dicoccoides*) associated with wild barley on the slopes of Mount Moab and Mount Galaad, in the valley of the Jordan, and on the plateau of Es Salt, always growing in thin soil, parched by the sun, in crevices of limestone and basalt rocks.

HOME-GROWN SUGAR-BEET SEED.

As a result of an experiment which has been conducted near Phoenix, Arizona, it has been found that sugar-beet seed can be grown successfully in that section of the country, and better still, that it can be grown in a single year. In Arizona it is customary to plant sugar-beet seed the latter part of November, harvesting the crop the following July. It has been found that if the seed is planted a month earlier in the fall the beets will produce a crop of seed the following year. This takes sugar beets, for that section of the country, out of the biennial class, and puts them in with the winter annuals. It means the saving of a year in the production of seed, and will greatly simplify the process.

Nearly seven million pounds of sugar-beet seed are used in the United States every year At present the bulk of this supply comes from Germany, and costs the American grower about ten cents a pound. The German method of producing sugar beet seed is rather complicated. When the beets are dug in the fall a number of the best specimens, averaging in size from 20 to 24 ounces, are selected for "mothers." A sample taken from each of these mothers is analyzed for sugar content. In some cases the density and purity of the juice are also determined.

These mothers are divided into grades, according to sugar content, and stored in silos during the winter Those that fail to come up to the required standard are discarded In the spring these mother beets are set out and cultivated carefully From them the seed of commerce is produced. By these painstaking methods the sugar-producing ability of the beets is kept up to its present high standard and even increased from year to year

Recently beet seed has been grown to a limited extent in the United States in Utah and Washington This home-grown seed has shown greater yielding ability than the seed from Germany The beets from home-grown seed have better quality and higher vitality, and seem better adapted to American conditions. Owing to the difficulty of production, however, beet-seed growing in Washington and Utah has not spread very rapidly

With more favorable climatic conditions prevailing in Arizona, especially the absence of severe winter weather and the dryness at harvest time, it may be possible to make beet-seed growing an important industry there Of course, since the beets are not dug in the fall, they cannot be selected as carefully as is done in Germany Whether the quality of the product can be kept up by other methods of selection remains to be proven Perhaps some method of breeding like that which is giving such good results in the corn fields of the Mississippi Valley may be adapted to sugar beets The United States Department of Agriculture has been asked to investigate the matter The results of this investigation will be awaited with much interest by the people of the sugar-beet growing districts.

THE PLATINUM MARKET.

Platinum is likely to be raised in price, according to the measures which the Russian producers are taking. About 95 per cent of all the platinum in the world comes from the mines at Nijni Taguil and the neighborhood The mines are now operated by English, German, French, and Russian companies but there is now a movement in Russia to keep the platinum production in the hands of a native company or a State enterprise so as to have Russia benefit by the platinum production instead of foreigners. Last spring the aide of the minister of commerce and industry, M D Konovaloff, presided at a meeting of the platinum producers, and the assembly came to the following decision in principle, namely, that all the platinum extracted in Russia should be turned over to a State establishment, which would deliver it to a commission charged with the sale of the same and to be composed of seven members, a delegate of the lesser manufacturers, one from the mean and four from the leading producers who handle more than 800 pounds annually, also a government delegate. This commission will make a reckoning before the end of the fiscal year, and will publish the least price established for the following year For the first year the price will be 21,000 roubles the pound ($710 per pound) for 83 per cent platinum Upon the products which are turned over to the State establishments there will be allowed an advance of 80 per cent of the value, at a 5 per cent interest. It will be forbidden to export crude platinum, and the refining must be done in Russia. This decision is not as yet legalized, but it may be done in the future, and it is expected that the price of platinum will be accordingly raised

A report on the resistance of rivets is presented by M. Ch. Fremont to the Bulletin de la Société d'Encouragement. It is pointed out that the resistance of riveted plates to statical forces or shocks should be borne as much as possible by the adhesion of the plates, and as little as possible by shearing of the rivets themselves, and the author emphasizes the necessity of standardizing the heads of rivets and of regulating the maximum temperature during the process of heating, so as not to destroy the elastic qualities of the rivet. The increased efficiency obtained by the application of continued pressure during the riveting is also mentioned.

[illegible] has to [illegible] miles between Ashokan [illegible], where it passes through salt-carry [illegible]. The erosion there is more rapid than [illegible] rest of the route, so that excessive leakage has [illegible].

Visitors to Admiral Seymour's flagship the "Inflexible," which is the only vessel of the "Dreadnought" type at the Hudson-Fulton Celebration, will be interested to learn that the new "Dreadnought" cruisers according to the British press are to be much larger and more powerful. They will have a length of 660 feet as against 560 feet, a total horse-power of 60,000 as against 50,000, and twelve 13-inch guns in place of the eight 12-inch carried by the "Inflexible."

There is a certain amount of sentimental interest attaching to the fate of a transatlantic record breaker and it is therefore gratifying to learn that the Cunard Company have arranged to accept $500,000 in settlement of the insurance on the recently burned "Lucania," and reconstruct this famous boat, making her thoroughly up to date in the matter of accommodations, etc. The "Lucania" was the first vessel to cross the Atlantic at an average speed of 22 knots.

It is gratifying to note that the large sea-going torpedo boats which are being built for the navy are making, on trial, speeds which are greatly in excess of the contract requirement. The "Flusser" built by the Bath Iron Works recently made between 32 and 33 knots on trial, and now a sister vessel the "Smith" built by William Cramp & Sons has made 32 knots on trial. Because of their large displacement of 700 tons these high speeds on trial mean much more than the high speeds achieved with our earlier boats, which have never approached in average day by day service the record made on their trial trips.

At the naval depot at Horton, Norway, the Norwegian government is refitting Nansen's old Arctic vessel, the "Fram," for another trip to the Arctic. A new gasoline engine capable of driving the vessel at four or five miles an hour is being installed, and a thorough overhaul is taking place. In a recent letter to the Norwegian consul at San Francisco, Capt. Amundsen states that he expects to leave San Francisco next June for the Behring Sea, where he will allow his vessel to be frozen into the ice and be carried by way of the Pole toward the northern part of Greenland. The "Fram" is about three times the size of the "Gjoa," now in the Golden Gate Park, San Francisco, in which Amundsen recently made his famous northwest passage.

Notice was recently given to the Treasury Department at Washington by the Pennsylvania Railroad Company that it proposes to operate its trains into the new station on the first day of December. In the great terminal between Seventh and Eighth Avenues and 31st and 33rd Streets there are sixteen miles of track, including twenty-one standing stations. Two tunnels connect the station with New Jersey and four with Long Island. Started in 1902, work has been carried on continuously ever since, and when the scheme is fully completed it will have cost over $90,000,000.

It will be remembered that at the opening of the Alaska-Yukon Exposition at Seattle the Great Northern Railway put on a 60-hour train from Chicago to Puget Sound. With the completion of the new Milwaukee, Chicago & St. Paul extension, the Maintenance of Way Department will bend their efforts to bringing the new track into such high-class condition as to permit of the running of high-speed through expresses from Chicago to the coast. The Milwaukee managers expect that next spring they will be in a position to offer a 54-hour schedule from Chicago to Seattle. This, coupled with the 18-hour service from New York to Chicago, will bring the time between New York and the coast down to three days.

The greatest possible interest attaches to the announcement that Mr. George Westinghouse, Rear Admiral Melville, and Mr. John MacAlpine have devised and built a reduction gear for interpolation between the steam turbine shaft and the propeller shaft for turbine-driven marine engines. The necessity for reducing the economical speed of the turbine to the economical speed of the propeller has long been manifest, and as we stated editorially last week, considerable effort has been directed to this problem. The helical [illegible] gear has been in use for many years on the De Laval turbines, but in the present device, by an ingenious construction of an automatically adjustable [illegible] it has become possible to apply this gear so as to transmit [illegible] horse-power, at 1,500 revolutions of the pinion per minute, at a reduction ratio of 5 to 1. It is claimed by Mr. Westinghouse that using this reduction gear, and with an inconsiderable loss from friction, it would be possible to apply the [illegible] horse-power of the "[illegible]" to three propellers, with a reduction [illegible] per cent [illegible] of the turbine [illegible]

AERONAUTICS.

Orville Wright, on September 30th, made another record for height while flying before the Empress of Germany and other members of the royal family at Potsdam. On this occasion, according to cable reports, he reached a height of 275 meters (902 feet). This is over 50 feet higher than his previous record made only a week before.

In connection with Berlin's aviation week, Hubert Latham made some excellent and startling flights recently. On the 25th ultimo he made a 20-minute flight above Tempelhofer field. The flight was terminated because of heavy rain. Two days later he made the most daring flight up to date, when in 24 minutes he flew from Tempelhofer field across Berlin to Johannisthal, where the aviation meeting was being conducted. The flight was made at a height of about 300 feet, the distance of 11¼ miles plus two circuits of the field (2.1 miles) upon his arrival being covered in 24 minutes.

Besides the exhibition of Curtiss's 60-horse-power biplane in Wanamaker's store in New York last week, another of these machines fitted with a 30-horse-power 4-cylinder motor was exhibited at the aeronautic show in Madison Square Garden. There were also two other similar biplanes, but one of which was fitted with a motor, however, and had made a short flight. The Braunier & Smith biplane resembled both the Wright and the Curtiss. It had the twin vertical rudders of the former and the single-surface horizontal rudder of the latter. C. & A. Witterman exhibited a strong, well-built biplane glider that attracted considerable attention. Several other gliders were shown, as well as numerous models, samples of balloon and aeroplane cloth, aeroplane parts, etc.

On October 1st, at the Berlin aviation meeting, Rougier with a Voisin biplane made an excellent endurance flight in which he remained aloft 2 hours 41 minutes and 50 seconds. Making 52 circuits of the field, he covered an official measured distance of 130 kilometers (80¾ miles) at an average speed of 30 miles an hour. Probably he actually covered over 90 miles in view of the many turns. The flight was only terminated because of approaching darkness. While Rougier's official record does not beat Farman's, it is encouraging as showing that a gasoline motor can be made to run for a long time on an aeroplane as well as on an automobile. The same day Farman flew 1 hour and 32 minutes, covering 82½ kilometers (51.23 miles) at an average speed of 33.41 miles an hour. Baron de Caters flew 18.6 miles in 34 minutes.

Just after we had gone to press with our last issue, which contained an article upon aeronautic accidents, the worst disaster of modern times occurred in France. Owing to the breaking of a propeller blade (which was projected clear through the balloon envelope), the new military dirigible "République" was almost instantly deflated, causing it to fall to the ground from a height of 500 feet. The four officers who formed the crew were all killed almost instantly. This disaster gives a strong argument in favor of the rigid-frame compartment dirigible of Count Zeppelin, which, it will be remembered, successfully went through a similar accident a few weeks ago. In this connection it is interesting to note that Wilbur R. Kimball had on exhibition at the preliminary aeronautic show last week in Madison Square Garden, New York, a model of a non-rigid dirigible which had a ring of small propellers completely surrounding it. He argues that small light wood propellers can be run at high speed without danger of breakage, while a greater thrust per horse-power is also attainable.

Owing to rainy and windy weather, the aeroplane flights of Wilbur Wright and Glenn Curtiss from Governor's Island up the Hudson River to Grant's Tomb and back did not take place last week as scheduled. Up to Saturday noon the only flights that had been made were a short half-mile jump by Curtiss shortly after 7 A. M. last Wednesday, and three practice flights by Wilbur Wright the same day. Two of these were made at 8.56 and 10.16 A. M., and were of 5 minutes 27 seconds and 6 minutes 32 seconds duration respectively. They were made in a strong westerly wind of about 20 miles an hour velocity. The first one consisted of the circling several times of the island, the machine flying most of the time at a height of 50 feet above the water. The second flight was much more sensational, for after circling Governor's Island as before, Mr. Wright flew over to Bedloe's Island and around Bartholdi's famous Statue of Liberty. After making all his great records in France it was particularly fitting that Wilbur Wright, in his first great public flight in America, should pay a visit to France's gift to her sister republic. These two flights, as well as the third one of 2 minutes 41 seconds duration, which was made at 5.25 P. M. in what was, if anything, an even stronger breeze, gave an excellent demonstration of Wright's ability to fly in a strong wind. It is probable that as soon as a reasonably calm day occurs he will make a record flight that will remain unbeaten for some time.

SCIENCE.

The United States Department of Agriculture is investigating the various methods of preserving eggs, for the purpose of determining which method is most efficacious and works least injury to the eggs. It has been discovered that the amount of moisture in the air surrounding the egg is an important factor in egg preservation, for which reason the Department is conducting experiments to devise a means for regulating the amount of air supplied to eggs kept in cold storage.

Col. Kozloff's Mongolian expedition, equipped by the Russian Geographical Society, has returned after twenty months of exploration in the region of the Andos Mountain range in Tibet. The chief discovery made was of the ancient city of Kharakhoto, called by the Chinese Siansin, which the Manchurians destroyed more than 500 years ago. The explorers found a great quantity of relics used in Buddha worship, a metal figure of Buddha perfectly preserved, and perfectly preserved manuscripts on canvas and silk in the Chinese, Manchurian, and Tibetan languages.

F. Fritz has discovered that the domestic cat possesses a peculiar organ of sense, consisting of a few long and stiff bristles or feelers which spring from a region of the skin richly furnished with nerves in the vicinity of the wrist joint of the fore leg. These organs, called carpal vibrissæ, had previously been found in numerous animals, including rodents, edentata, carnivora, the lower quadrumana, and *Hyrax*. They are found chiefly in animals which hold their food with their forepaws or which crawl and climb. Thus they are wanting in the ungulata, with the exception of *Hyrax*, and also in the apes and monkeys, which possess in their fingers and palms much more delicate tactile and prehensile organs. It is remarkable that they are also wanting in the dog, in which animal Fritz has sought them in vain.

The Académie des Sciences recently awarded a number of prizes for scientific work. In mechanics, M. Lecornu, professor at the Polytechnic College, received the Montyon prize, $140; M. de Sparre, the Poncelet prize, $400; M. Boulanger, the Boileau prize of $260. In astronomy the Lalande prize of $108 was awarded to M. Borelly of Marseilles. For navigation, the grand prize of the marine, $1,200, was divided among Messrs. Colin, Jeance, Marber, Doyère, Lecocq, Timot, and Fromaget. The Plumey prize of $800 was awarded to Messrs. Routier and Caralp. In mineralogy and geology the Raulin prize of $30 was given to M. Leon Bertrand, and the Labbé prize of $200 to G. Rolland. Prof. Mercadier of the Polytechnic College received the Pierson-Perrin prize of $10,000. The Delesse geological prize of $280 was awarded to Prof. Glangeaud of Clermont. In medicine a number of prizes were awarded, among which was the sum of $800 given by the academy itself to Dr. Haffkine for his work on vaccination for cholera and bubonic pest. The academy also distributed the second annuity of $[illegible] coming from the Bonaparte fund among different workers in the scientific field.

A letter has been received at Harvard College Observatory from Prof. C. C. Comstock, Director of the Washburn Observatory, giving the following finding ephemeris of Halley's comet derived by him:

Perihelion Passing April 18th

Paris M. T. 1909	D	R. A. H	M	Dec. Deg	M	Mag
September	[illegible]	[illegible]	19 3	+17	7	[illegible]
	[illegible]	6	18 8	1[illegible]		
October	2[illegible]	6	17 8	17	3	14 8
	7 5	6	16 0	1[illegible]	1	
	1[illegible] 5	[illegible]	11 4	16	[illegible]	14 [illegible]
	17 5	6	9 8	16	8	
	2 5	[illegible]	4 9	16	[illegible]	14 1
	27		[illegible]8 9	1[illegible]	4	
November	1[illegible]	5	[illegible]1 3	16	[illegible]	1 [illegible]
	6 5	[illegible]	4[illegible] 1	16		
	11.[illegible]		30 [illegible]	+16	47	13 4

The above ephemeris is derived from that of Holetschek, Astro. Nach. 4330, by interpolating the time of perihelion passage so as to satisfy observations made by Burnham and Barnard September 1[illegible]th and September 17th respectively.

A letter has been received at this observatory from Prof. E. B. Frost, director of the Yerkes Observatory, stating that Halley's comet was observed visually by Prof. E. E. Barnard on September 24 d. 20 h. 2[illegible] m. 21 s. G. M. T. in:

App. R. A. [illegible] h. 18 m. 56.72 s.

App. Dec. +1[illegible] deg. 6 m. 11.2 s.

Comet followed comp. star 0 m. 19.0[illegible] s. by 8 direct measures.

Comet north of comp. star 0 m. 39.4 s. by 9 direct measures.

The comparison star was Berlin A. G. 2122.

The comet was considerably brighter than on the 17th; estimated as 15th mag.; measured diameter 11 s.; indefinite condensation almost amounting to a small nucleus; no definite boundary."

STEREOSCOPIC MOVING PICTURES IN NATURAL COLORS

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

During the past few months several devices have been perfected for producing moving pictures in their natural tints all carried out upon the same lines. All suffer from the same disadvantage—the color rendition upon the white screen is imperfect and untrue. Mr William Friese-Greene, F. R. A. S., F. R. M. S., exhibited in London as far back as 1898 a series of animated natural color pictures. The system which he duly patented was to revolve a disk of glass divided into three equal sized sectors each representing one of the three fundamental colors and revolving it in front of the lens as the exposures were being made, each section of the sensitized film (corresponding with the size of the ordinary cinematographic picture) being exposed through one of the three color filters. In making the subsequent projection the colored disk was again revolved in such a manner that the same relationship of picture to color filter that prevailed during the exposure of the negative was repeated. The rays of light consequently passed through the black and white film and thence through the color filter. The resultant picture was projected in accordance with the well known phenomenon of visual persistence producing the impression of a complete three-color image.

The demonstration aroused considerable interest but the inventor soon realized that such a system possessed one serious disadvantage. The glass disk had necessarily to be of a certain thickness—from one sixteenth to one twelfth of an inch—so that there was a certain depth of transparent glass through which the light rays had to pass before or after reaching the color filter depending on whether the color side of the disk was next to the transparent film or reverse. This fact produced disturbances in light refraction and reflection, of such a severe character that the projected image as seen upon the white sheet was a color distortion and a crude reproduction of nature. The extent of the deflection of the light rays in passing through the transparent thickness of the glass disk varied considerably and in the resultant picture occurred an undue predominance of one or two colors, which completely destroyed the natural effect. It is this system which is now being developed by various experiments in the field of chromo-photography, but which the original inventor abandoned for the foregoing reasons.

Fig. 4.—Front view of stereo-chromo-cinematograph projector, showing how the twin lenses are alternately exposed by the shutter.

Fig. 5.—A three-quarter view of the stereo-chromo-cinematograph, showing the mechanism for carrying the endless color band.

By continuing his experiments Mr Friese-Greene was enabled to overcome all the incidental difficulties inherent in his first apparatus. He abandoned the revolving glass disk and resorted to a prism placed in front of the lens. This yielded a much more satisfactory result but was naturally somewhat primitive and commercially impracticable. Recently, however he has completed and patented an entirely new system, which together with many other important improvements he has effected in connection with the apparatus itself (both camera and projector) and also in the preparation of the sensitized films promises to improve chromo-photography.

Through the courtesy of the inventor the writer was afforded an opportunity of examining the apparatus and the whole process of taking and projecting films by this new system for the SCIENTIFIC AMERICAN while the accompanying illustrations, specially taken for these pages serve to show the camera and its method of operation. At the time of writing some twenty films had been secured depicting varying scenes in natural life from incidents in busy streets to studies of insects and growing flowers. Not only are the color effects obtained, but they are stereoscopically projected. The effect produced upon the screen is precisely the same as that obtained with ordinary stereoscopic photographs when observed through the hand instrument devised by Oliver Wendell Holmes.

With this apparatus moreover, a continuous picture is obtained, which is not the case in the ordinary machine. In the latter instance as is well known the

The handle at the left drives the photographing mechanism, while on the right the sighting device is shown closed.

STEREOSCOPIC MOVING PICTURES IN NATURAL COLORS.

ERECTION OF THE FADES VIADUCT

BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

A piece of bridge construction work presenting some noteworthy features has recently been carried out in France. It is known as the Fades Viaduct and is designed to take the railroad across the wide valley in which flows the river Sioule The present work is notable for two reasons, one of these being the exceptional height of the masonry pillars, which are built in the valley, and in the second place for the considerable length of the central span The viaduct has the form of a straight iron lattice-work bridge construction. It is carried upon two lofty piers and two abutments the length of the consecutive spans being 383 feet 475 feet and 383 feet. The flooring of the viaduct lies at a height of nearly 440 feet above the level of the Sioule The height of the great masonry columns of rectangular section is 304 feet and they appear to be the highest pillars for a bridge built in Europe up to the present The whole undertaking reflects great credit upon the constructors the well known Cail Company and the work was carried on under the general direction of its chief M *Le Chatelier from* whom we have obtained the following points The most difficult part of the work was to make the junction between the overhanging halves of the central span This was carried out on the 18th of May last and the operation was performed with remarkable precision To make *the junction the whole bridge had to be lifted off the* two main columns by hydraulic jacks in order to make up for the slight sinking of the two fore ends and bring these exactly opposite each other and in true line After joining the ends the bridge was lowered again upon its supports The present viaduct lies upon the railroad which runs in the southeastern part of France in the region of Clermont Ferrand and is built upon the section which runs between Saint Eloy and Pauniat On each side of the 475 foot central span there is a side span of 383 feet In the rear of the stone abutments there is an approach to the main structure consisting of a small masonry arch of 46 feet span on one side and at the other end is built a 162 foot truss span The two main stone piers sup-

ERECTION OF THE FADES VIADUCT.

porting the central span of the viaduct are built to a height of 404 feet above their foundations. These latter are carried down to a depth of 40 feet for the pier lying on the left bank, which makes the total height of the stone work to be 344 feet. For the foundation on the other bank the depth is somewhat smaller making the total height of the pillar to be 312 feet The bridge is constructed for single track standard gage, and is built of a rectangular cross section consisting of two main side lattice trusses 38 feet deep, which are spaced 22 feet between centers. Upon the top are laid the floor beams which serve to support the stringers, and upon those rest the rails of the track The sway bracing is spaced at intervals of 48 feet. In order to allow for expansion and contraction, the structure is fixed at one of the abutments only while upon the two main pillars and the other abutment it is mounted upon a movable support of the usual kind.

In constructing the bridge it was not found possible to use the method which consists in building the spans on the ground back of the site and then driving them forward into place seeing that there was not the available space for carrying this out. Another method, therefore, had to be employed, and it consisted in the use of a scaffolding which is mounted under the side spans. The bridge was built from the abutments to the end of the scaffolding and from this point it was built across on the overhanging principle until it reached the main piers, falsework being used below the first half of the span One of the characteristic features of the work is the erecting of the bridge in the overhanging portions In order to carry this out there was used a cage-like traveler, which ran along upon the outside and surrounding the truss It traveled upon rails which were laid upon the top of the truss and upon the two sets of rollers. Measured from the flooring and from the back end of the cage the first roller lies at 13 feet and the second at 40 feet distance, representing the end point of the truss, but the fore part of the cage projected out from the finished end of the truss with an overhang of 33 feet. On the inside of the truss there was a corresponding structure built of timber Upon it were three working platforms, arranged to give access to the different heights. Supported from the inner timber structure and also from the outer cage there were hanging platforms which were let down by pulleys, for the workmen who operated the compressed air riveters These latter were hung down at the level of the platforms by traveling carriages, which ran upon upper rails at the top of the cage. On the top was also mounted a large traveling erecting crane designed to take the beams and other material from the back end and bring it forward to the working point. In this way the work advanced at the average rate of 3 feet per day The trusses were thus brought forward to the main piers at each side They were built forward in the same way to form the middle span When the halves of the middle span met they deflected below the normal position, and it was necessary to lift them to their true level The operation was carried out by raising the trusses off the piers by hydraulic jacks, and at the same time lowering them at the abutments, thus tilting up the spans as a whole and allowing the ends to match at the middle. Upon the piers where the weight was 1 200 tons, there were used for the lifting four hydraulic jacks of 300 tons each. The base of the jacks rested upon a set of rollers, so as to give the needed movements. A small 8-ton hydraulic jack gave the lateral movements which were required In this way the two trusses were raised and brought into exactly the proper position at the meeting point. When this was done the chords were joined by temporary bolts at first, so as to complete the truss from end to end, making a continuous structure The bridge was then raised at the abutments and finally lowered into place upon the pillars, so as to bring it to its normal position.

German-American Patent Treaty.

The American Association of Commerce and Trade in Berlin issues the following announcement prepared by Henry Schmidt, on the effect of the new patent treaty between this country and Germany

The new patent treaty between the United States and Germany which went into effect on August 1, places American citizens on a decidedly better footing in regard to the utilization of patent protection in Germany as it frees them from the obligation to work their patented inventions in Germany within three years from the granting of the German patent. Heretofore any failure to comply with this working obligation would in the case of an action for revocation of the patent being brought against the patentee result in the loss to him of his German patent.

This is no longer to be the case with the German patents of United States citizens, as the new treaty provides that the working of a patent in the territory of one of the contracting parties shall be considered as equivalent to its working in the territory of the other party Hence an American citizen who works his United States patent in the United States will no longer be required to work his corresponding German patent in Germany in order to avoid loss of his German patent in case of an action for revocation being brought against him.

The question as to whether the provisions of the treaty are to apply also to existing German patents in regard to which the three-year term allowed for working already expired before the date on which the treaty went into effect, is not decided yet, but many persons are of the opinion that even such patents will now be entitled to the benefits of the treaty, provided that no action for revocation was actually entered prior to that date. At any rate, it may be assumed that, in addition to all German patents applied for after that date, such older patents in regard to which the three-year term extends beyond that date will enjoy the benefits of the treaty.

This new treaty, abolishing, as it does, a condition of affairs that has been felt as a hardship by American inventors, will no doubt induce many American inventors to apply for German patents in cases in which they would otherwise have abstained from so doing.

Electricity and Vegetation in Polar Regions.

Electroculture is an old subject, upon which opinions are still at variance. Some investigators have definitely rejected the hypothesis that vegetation is affected by atmospheric electricity On the other hand, Prof Lemstroem of the University of Helsingfors, Finland vigorously sustains this theory and adduces experimental evidence in its support. Lemstroem asserts that when plants cultivated in the polar regions escape destruction by nocturnal frosts, they grow far more rapidly and luxuriantly than plants growing in milder climates. Rye, barley, and oats, especially, yield very large crops, in spite of primitive methods of cultivation with wooden plows and harrows. The growth of plants depends not only on the fertility of the soil, but also on the supply of heat, light, and moisture In the polar regions the supply of heat is very small The rapid growth of plants in these regions has hitherto been attributed to the continuous daylight of two or three months in summer, but this explanation must be abandoned, since it has been proved that, even in those months, less heat and light are received from the sun in the polar regions than at the latitude of 60 degrees. Lemstroem finds several reasons for believing that the cause of rapid growth in the Arctic is to be found in the electrical currents which flow between the earth and the atmosphere and produce the phenomena of the aurora borealis The pointed leaves of conifers and the barbs of ears of grain facilitate the transmission of these currents through those plants, and this function supplies a reason for the existence of these peculiarities.

From a study of the concentric annual layers of growth of conifers growing in various latitudes, between the 60th and 67th parallels, Lemstroem finds that the thickness of the annual layer varies according to a definite law, showing maxima and minima which indicate a period of ten or eleven years, coinciding with the period of sun spots and auroras. The differences, furthermore, are greater in the great firs within the Arctic circle, at 67 degrees north latitude, than in trees growing further south This appears to indicate that the atmospheric electricity of the polar regions exerts a beneficial effect upon vegetation

Lemstroem has also made experiments on the effect of electricity, produced by a Holtz machine, upon barley, wheat, and rye, growing in pots and in the open ground The results of these experiments appear to him to give support to his theory of the favorable influence of electricity upon the growth of plants.—Cosmos.

The Current Supplement.

The opening article of the current SUPPLEMENT, No. 1762, discusses in a most interesting manner the caisson method of sinking the Detroit River tunnel. Excellent illustrations accompany the article. "Platinizing or Platinum Plating" is the title of an article which gives some very interesting technological information. The comparison of the phonograph and photograph by Dr R. Defregger in an article entitled "The Analytic Eye and the Synthetic Ear" illustrates the contrasts between the senses of sight and hearing. Our impression of the universe, as the article points out, would be curiously different if the functions of these two senses were interchanged, so that the ear would perform the work of analysis and the eye the work of synthesis Thomas W. Relph discusses the different practices of illumination. He points out that in the field of illumination practice is several thousand years old, while theory is only beginning to be developed. He gives also helpful suggestions as to proper illuminations for various types of interiors. A résumé of some recent processes for the fixation of atmospheric nitrogen is presented. L. Zehnder writes on the dangers of atmospheric electricity in aeronautics. A telephone system for Peking is described. G. Millochau of the Paris Observatory discusses the subject of stellar evolution and the origin of worlds. How water and milk may be [illegible] with [illegible] is pointed out by F. [illegible]. The great monumental structures of the later stone age were apparently erected without the employment of any more elaborate machinery than levers and rollers from trunks of trees. A discussion of the wonderful monuments thus erected is presented. Dr. George M. Gould's paper on the rôle of visual function in animal and human evolution is published.

The Highest Balloon Ascension in America.

Although a large number of *ballons-sondes* were dispatched from St. Louis in 1904-7 under the direction of the writer, none had been employed in the eastern States until last year. In May and July, 1908, four *ballons-sondes* were launched from Pittsfield, Mass., with special precautions to limit the time they remained in the air and so prevent them from drifting out to sea with the upper westerly wind. Three of the registering instruments have been returned to the Blue Hill Observatory with good records. The first instrument sent up on May 7th was not found for ten months and the record, forming the subject of the present article, is very interesting because it gives complete temperature data from the ground up to 17,700 meters, or 11 miles. This is 650 meters higher than the highest ascension from St. Louis, which, by a coincidence, was also the first one to be made there. On May 7th a general storm prevailed, so that the balloon, traveling from the east, was soon lost in the cloud and its subsequent drift could not be followed, but the resultant course was 59 miles from the southwest, as determined by the place where the instrument fell two hours later At the ground the temperature was 4.5 deg. C., and this decreased as the balloon rose to the base of the cloud, which itself was considerably warmer than the underlying air. Above the cloud the temperature continued to fall with increasing rapidity up to a height of 12,500 meters (nearly eight miles) where the minimum of —54.5 deg. C was registered. Here the great warm stratum was entered and penetrated farther than ever before in this country, namely, to the height of 17,700 meters, where the temperature was —45 6 deg. C. An increase of 10 deg occurred, however, in the first 3,000 meters, for above 15,500 meters nearly isothermal conditions prevailed, confirming the belief of Teisserenc de Bort that what he calls the "stratosphere" is composed of a lower inverting layer with isothermal conditions above extending to an unknown height. In an ascension last November in Belgium the relatively warm stratum was found to extend from 12 900 meters to the enormous height of 29,000 meters, or 18 miles, where there was still no indication of its diminution.—A. Lawrence Rotch in Science.

Glass Espalier Walls.

When vines and trees are trained in espaliers on the south side of a wall, the north face of the wall is usually wasted, although it can be used for the cultivation of varieties of apples, pears, and cherries which are hardy and not subject to rot. If a transparent wall could be used, plants growing on both sides of it would receive the benefit of the sun's rays. Some experiments have been made with glass walls. Count de Choiseul recently published the results of such an experiment, with photographs showing heavily fruited pear trees on both sides of the transparent wall The wall, which is about 60 feet long and 6½ feet high, was erected in 1901. Each side of it was planted with 15 pear trees of the variety *Doyenne d'hiver* (Winter Doyen), giving a wall area of 232 square feet to each tree. In 1907 the trees on the south side bore 134 pears, weighing 91 pounds, and the trees on the north side bore 109 pears, weighing 77 pounds. All the pears were of very fine appearance and without blemish, and the pears from the north side were smoother than the others.

In the nursery of Croux et Fils is a glass wall, which is surmounted by horizontal glass sashes and planted with the same varieties of peaches, apples, and pears on each side. These espaliers also began bearing in 1907, and both sides have produced equally fine fruit. The difference in temperature between the sides of the wall is not very great, as the southern face reflects less heat and is therefore cooler than that of a masonry wall, while the northern side is warmed by the rays which pass through the glass. A masonry wall possesses, theoretically, one advantage over a glass wall, as it absorbs during the day a greater quantity of heat, and consequently exerts a greater heating effect at night. Longer experience will be required to determine which material is the better on the whole. The cost of construction is practically the same for both.—Cosmos.

LATHER AS A TRAP FOR INSECTS.

To the Editor of the SCIENTIFIC AMERICAN

Here is a little experience that may be valuable to others:

An hour ago, while I was reading my SCIENTIFIC AMERICAN, my room was invaded by a swarm of gnats, and I was unable to continue my reading. Just as I was wishing I had sticky flypaper, I thought of something else. I took a cake of toilet soap and made a quantity of stiff lather, and spread it on some sheets of paper which I laid in the bright light under my lamp. I also covered the top of the lamp around the burner with the lather In fifteen minutes every gnat had got tangled in the lather, besides a candle moth or two for good measure As I was reading your paper at the time I thought it might be useful to you, so here you have it. L. L. KLINEFELTER.

Obar (formerly Perry), N M.

THE POPE AND THE COMET

To the Editor of the SCIENTIFIC AMERICAN

I regret that you have published the old fable of the Pope and the Comet. Kindly correct it in the name of truth. (Rev) H S SPALDING, S J

Chicago, Ill.

In an article published in Popular Astronomy last October, William F Rigge considers this subject He writes

"It seems that no article can be written on Halley s comet without bringing in the oft-told story of the bull which Pope Callixtus III so ineffectually launched against it, or of the Angelus bells which were rung to frighten it away, or of the prayers which were to deliver the Christian world from the devil, the Turk, and the comet. The truth-loving reader will therefore, be probably most intensely surprised when he hears that, as an actual fact of sober history there is no truth whatever in the story, not even in its least details. And the proof is easy and solid.

"First. While Newcomb calls the bull a myth, but along with the Columbian and Chambers encyclopedias believes that prayers were ordered to be said against the comet, no allusion whatever to the Pope, the bells and the prayers is made by Sir John Herschel, Grant, Young, Comstock, Todd, Langley, the American Cyclopedia, the Encyclopedia Americana, the Encyclopædia Britannica of 1902, etc While this may be a negative argument, it is not, however, an inconclusive one for why should these eminent authorities, all of them non-catholic, not mention the story if it is true, when so many other writers speak of it?

"Second. The Bullarium Romanum is a large series of volumes containing in Latin most of the official documents ever issued by the popes, from St. Peter down to our own day. Owing to the definiteness of the reference and the short reign of Callixtus III, it was an easy task for me to read all the documents of this pope, and I can attest from my own personal knowledge that not only is there no bull against or concerning a comet, there is not even a paragraph, nor a phrase, nor a word, which might be construed to refer to a comet.

"Third. The story is so universally told and is to be found in so many writers, such as Arago, Draper, Babinet, Guillemin, White of Cornell, etc., that most persons are really excusable when they are misled into the conviction of its truth, and then simply copy it and pass it on to the next generation If the reader of these lines is really interested in the matter, I would refer him to an able article entitled "Of a Bull and a Comet" written by John Gerard, S J, and published in The Month, London, in February, 1907 Here the whole story is traced to its fountain head, and it is shown by the best authorities, nearly all of them non-catholic, that not only no bull was ever launched against the comet, but prayers were not even ordered to be said against it, although the prevailing opinion of the scientific men of the time was that the comet foreboded calamity to the earth Any one that wishes it may obtain a free reprint of the article in question by applying to the Superintendent of Parish Schools, Broad and Vine Streets, Philadelphia.

"Fourth. The article just referred to traces the origin of the whole story about the bull against the comet to this one paragraph of Platina, in his Vitas Pontificum, published in Venice in 1479 As this writer was not only in Rome at the time, but was also archivist of the Vatican when he wrote his history, his authority ought to be of the utmost value. These are his exact words:

"'A hairy and fiery comet having then made its appearance for several days, as the mathematicians declared that there would follow a grievous pestilence, dearth, and some great calamity, Callixtus—to avert the wrath of God—ordered supplications, that if evils were impending for the human race, He would turn all upon the Turks, the enemies of the Christian name He likewise ordered, to move God by continual entreaty, that notice should be given by the bells to all the faithful, at midday, to aid by their prayers those engaged in battle with the Turk.'

"Let us read the words again and study them carefully 1. The Pope did not issue a bull against the comet, he ordered supplications 2 He ordered these conditionally 'that if evils were impending,' prudently neither admitting nor rejecting the authority of the mathematicians who declared that pestilence, dearth and some great calamity would follow the appearance of the comet. 3. He assumes no authority over the comet nor bids it be gone he orders supplications, declaring himself to be a suppliant, that if evils were impending, God would turn them upon the enemies of the Christian name. 4 Bells are to be rung to remind the faithful to pray, not to frighten away the comet.

"This one quotation from one author, which has been the germ of the whole comet story, weakened as it is by our simple analysis, becomes of no value whatever when we apply the rules of ordinary historical criticism. We have only the word of Platina that the Pope ordered supplications to be made and bells to be rung, he neither refers to any papal document nor does he quote the Pope s exact words. Now, as the Bullarium Romanum contains all the official documents of all the popes, and as not one of the declarations of Callixtus III alludes in any manner whatever, directly or indirectly to a comet, we have every reason to dismiss the testimony of Platina altogether For this same reason we must also reject the testimony of each and every writer that mentions the comet story or any of its details, because not a single one of them has ever given the slightest reference to any official document ever promulgated by Callixtus III whether in the Bullarium Romanum or out of it, nor supported his assertion by anything stronger than a quotation from a previous writer who was equally deficient in his historical *proofs*

"There is, therefore, no foundation whatever for the *story* that Callixtus III issued a bull against or concerning a comet, that he ordered bells to be rung to *frighten* it away, and that he ordered prayers to be said to deliver the world from its influence '

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN

If all of one's progenitors had been totally unrelated, each generation back would consist of twice as many persons as the one preceding it. But the true number of one's ancestors would in a few generations cease to even approximate the figures thus obtained

It is likely that after going back just a few generations, the number of ancestors in each degree would remain fairly constant. In many instances of small isolated communities it is possible that the eighth to tenth remove might include the entire community at that time From that point, the number would bear a definite relation to the population, and would often be a decreasing factor

It may be inferred from the persistence of some strongly developed types, that persons of the same ancestry are drawn together by natural selection without any knowledge of their common parentage, as most people's knowledge of their own genealogy becomes hazy when the third generation is passed In fact, it generally ends there There is not one person in a thousand that can name all his great-grandparents

It seems to me the probabilities are that when a generation includes as many as one thousand persons, that number is not likely to be exceeded by any previous generation, and I do not believe that number would be reached ordinarily in less than twenty generations.

The tenth-degree ancestors would number 1 024 if there were no deductions by reason of plural lines of descent from some of them

F W A shows that the second third, and fourth degree ancestors may number only four each Blackstone in his Commentaries on English Law using a very similar illustration, shows that an indefinite number of generations might consist of but four persons each and that *all the unions might still be legal* Twenty generations of legal ancestors might then comprise *only seventy-eight persons, and it seems probable* that this number is nearer the truth than the enormous number suggested by the first contributor

The theoretical number of ancestors in ten generations would be 2,046, but suppose that in each generation from the third to the tenth there was one from whom there were two lines of descent That alone would reduce the number 492 or nearly one-fourth. The more remote in degree, the greater would probably be the proportional loss by lines running to a common source.

There can be no approximation to the true number that would be more than a more or less shrewd guess—my own is no better than anyone else s—and it is that in twenty generations the total number of one's ancestors is not likely to exceed 20 000 or an average of 1 000 to the generation and that the number in each preceding generation is more likely to decrease than to increase

After arriving at the true number of one's ancestors in each degree, if that were possible, the total would be subject to considerable deductions on account of the same person s being an ancestor in several different degrees, as would be the more likely the more remote the relationship. R L. FLOYD.

El Dorado Ark

THE NUMBER OF OUR ANCESTORS AND OF OUR FUTURE COUSINS.

To the Editor of the SCIENTIFIC AMERICAN

The problem which has been discussed by a number of your correspondents, in regard to the number of our ancestors, while very puzzling has given rise to another quite as puzzling to my mind and even more disquieting.

It appears evident that to have kept good the number of the human race, or of any other race each pair must on the average have produced two offspring who matured and reproduced themselves in two individuals, and so on, this merely on the supposition that the number of the race remained stationary although it is generally supposed the human race has increased through the ages However adopting the first *supposition, as very moderate surely, I cannot* escape the following conclusions

A has two parents each of whom had *one* brother or sister and each of these collateral relatives has two children Therefore A has four first cousins or four cousins of his own generation descended from the collateral branches one generation back. Likewise from the four collaterals to his grandparents he has sixteen cousins of his own generation from the eight collaterals to his great grandparents he has sixty-four cousins of his own generation, etc or in general A has 4^n cousins of his own generation descended from ancestors n generations back

This gives us startling results From the ancestors ten generations back A has over a million cousins fifteen generations back over a billion, and this takes us back only about five centuries If we go back another century or eighteen generations, A must have about 64 billion cousins and we are still in very modern times.

Now, what has become of all these myriads of cousins? *They are not on the earth* Where are they? And worse yet because it looks to the future what of A s children? They must have four times as many cousins as he, and his grandchildren must have sixteen times as many The prospect looks dark to me I am more concerned about the cousins of the future than I am for the ancestors of the past

WHY DO MAIN SPRINGS BREAK?

To the Editor of the SCIENTIFIC AMERICAN

Inasmuch as I have had over thirty years experience in fitting some thousands of main springs to watches I believe that I may be able to add something *to the article entitled* 'Why Do Main Springs Break?" which appears in your issue of September 4th 1909

I have found in my experience that the main spring of new watches break when the watch has been in use only for a few days. The cause may be attributed to the excessively high tempering of the steel, and in some cases to the uneven tempering of the steel Moreover any mineral or vegetable oil will corrode the main spring because of the presence of acids in the oil During my entire experience I have never been able to obtain any mineral or vegetable oil free from acid The only oil that I have used with success is purified fish oil

I have found that main springs also break into many pieces because the watchmaker has carelessly handled the spring with perspiring hands. Some watchmakers when cleaning a watch steep the main spring as well as the other parts either in benzine or kerosene to save time This practice will surely cause the main spring to break within a very short space of time, because of the acids in the benzine or kerosene which penetrate the steel Even though the spring be afterward *oiled with good fish oil* it is sure to *break after* this dipping in kerosene or benzine

If a barrel arbor around which the main spring coils is made too small in time the spring will break close to the center which is an infrequent occurrence particularly in modern watches

When the watch repairer finds that a spring has lost its resiliency instead of replacing the old spring with a new one, he will sometimes take the spring in his hands and straighten it by drawing it between his thumb and fore finger thus restoring its resiliency temporarily At the same time however he makes the spring more brittle and breakage is sure to follow such treatment

In conclusion I wish to concur with your contention regarding the breakage of main springs during hot weather particularly when taking the watch from the pocket and laying it suddenly on a cold marble or iron slab RICHARD B SMITH

OPEN-AIR ORCHARD HEATING IN COLORADO

BY W. FRANK McCLURE

The 1909 crop of fruit in the Grand Valley in Colorado from the Palisades above to Loma below valued at $3 000 000 owes its existence to a unique battle which was waged against Jack Frost at a time when the fruit was at its tenderest age. By unusual generalship and the work of hundreds of enthusiastic volunteers the temperature in these orchards was actually raised eight and nine degrees over 27 miles of territory and a precedent was established which will mean much to the future. In California it is said that the temperature has been raised heretofore in some single orchards two or three degrees but never to eight degrees and never before has the work been carried on over so great an area. Plans are now on foot to have every bearing orchard in the Grand Valley protected by next season not that there is any likelihood of frost every spring in this section but because the protection against possible repetition of this year's experience is considered cheap insurance. Representatives of other fruit growing sections have also recently visited the Grand Valley sent there from their several communities to learn more of the recent experiment.

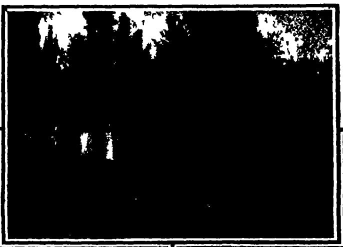
One of the many different styles of pots used in smudging.

An oil pot with hood in place.

Another type of pot in which oil is used.

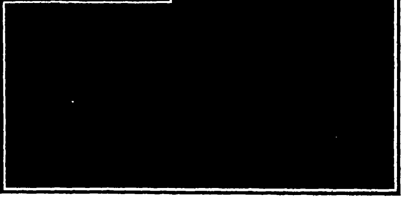
The raising of the temperature over this large area was accomplished by means of some 300 000 smudge pots of many different types some burning oil for fuel and some coal and placed at intervals in the orchards after the manner shown in the accompanying photograph. Oil was carried to the pots in wagon tanks equipped for the purpose. Spraying machines were also used in distributing the oil. A large supply of lighters was kept in readiness in a dry place. Many of these lighters were made by wrapping waste about a twisted wire.

All operations were directed from Grand Junction. Weather stations established over much of the territory and equipped with thermostats when the threatening weather arrived made half hourly reports on the temperature to Grand Junction.



Spraying the trees with apparatus which also conveys oil to the pots.

Raising the temperature in a Colorado orchard.



A photograph taken late in the evening, showing coal pots with draft covers set

When finally the danger point was approaching warning was sent to all the ranchmen to light the fires. Volunteers also in nearly all walks of life made their way in automobiles and wagons and on bicycles over the entire area. The Trades and Labor Assembly adjourned its meeting and worked all night rendering assistance. Men worked in shifts, some at night lighting the fires, and others in the daytime filling the pots. Even women assisted in the work. The campaign in all lasted four days.

So well did this orchard-heating idea work, that while the temperature outside the heated area dropped as low as 20 degrees within the heated area it did not go below 29½ deg. Seventy five per cent of all the fruit trees which were in bloom were cared for directly while even orchards owned by those who were skeptical of the idea were saved by the fires in the adjoining territory.

As previously stated there were a great many different kinds of pots used in this work. The number used per acre depends upon the size. Forty 60 or 80 pots per acre was the average. When coal is used it is usually lump or nut. With coal at $4 a ton some one has figured that it cost him $4 per acre to heat his orchard for a six hour run. Some of the oil heaters are used to the number of 60 or 80 to the acre. In the opinion of some it is better to have a small-sized pot and use more to the acre, say 60 or 80, as just stated.

Taking one of the many kinds of pots as an example and figuring coal at $4 a ton the cost of equipping with heaters and all other facilities for the first year for ten acres is estimated at $449 25 and for the second year $186 25. This provides in the initial cost for 800 heaters, or 80 to the acre. It also provides for 40

Typical Colorado orchards; young trees in the distance.

OPEN-AIR ORCHARD HEATING IN COLORADO.

tons of coal, kindling lighters, 50 pounds of waste, 200 gallons of oil for lighting, the storage for oil, and the building of a coal house. For the first year's equipment for oil pots, including 800 pots for ten acres, and fuel at 5 cents a gallon, the cost is estimated at $494.35, and for the second year $153.75

Now that the question of raising the temperature even 10 or 15 deg. over a large area has been settled beyond doubt, the next problem facing the fruit growers is that of regulating the temperature and economy of fuel and labor For example, there is no need of raising the temperature 10 deg. when raising it 2 deg. will put the blossoms out of danger Some are planning to meet this problem by having a large number of small pots and only light enough of them to keep the temperature above the danger point. Others have devised pots with a system of drafts, so that the heat may be increased or decreased as is necessary

The fruit ranches of the Grand Valley are very extensive. One, for example, contains 243 acres, and is valued at a quarter of a million dollars. Its crops include peaches, apples, pears, plums, cherries, and soft-shell almonds. An army of people is required to pick the fruit. By another season it is expected electric lines will be running out to the orchards all over the valley, and refrigerator cars will be carried right to the orchards.

THE VISITING WARSHIPS—A COMPARISON

Because of incompetence in its management the naval parade, which should have been one of the most attractive features of the Hudson Fulton Celebration, came very near being a complete failure, and it was only redeemed by the fact that its line of travel lay parallel with the finest assemblage of warships that was ever gathered in the waters of the Western Hemisphere The very devil of mischance seemed to have been abroad on the morning of September 25th, and he became busy at the very outset, when the "Half Moon," in a laudable endeavor to show herself under sail, had no sooner spread her canvas, than she plumped squarely into the "Clermont," and came very near ending the career of that little craft there and then. The two great errors which made the parade a failure were, first, the anchoring of the "Half Moon" and the "Clermont" off 110th Street, instead of sending them under tow around the whole line from 42nd to 205th Street, and secondly the failure to dispatch the commercial steamers tugboats yachts etc two or three abreast and with reasonably short intervals between them As it was a vast part of the visitors both ashore and afloat, all, in fact who were above 110th Street, never caught a glimpse of the two vessels, the "Half Moon" and the "Clermont," in whose honor the parade was being held Instead, for them the procession consisted of a lot of detached and widely separated passenger steamboats big and little, which

steamed leisurely around the fleet—vessels with which the majority of the spectators were already perfectly familiar, from the Hendrick (sic) Hudson" down to our venerable friends the "Iron Steamboats."

It was the noble line of warships, nine miles in length however, that saved the day At the head of the line above Spuyten Duyvil, was the turbine-driven 26 knot scout cruiser 'Salem" Astern of her were the armored cruiser "New York" the flagship of Admiral Sampson during the Spanish war and now fresh from a one million dollar overhaul in which she has been brought as far up to date as a ship of her age can be Then there was the North Carolina," a handsome modern armored cruiser of the pre-'Dreadnought" period Below these in majestic array came the sixteen battleships which made the memorable voyage around the world Astern of these was the Dreadnought" cruiser "Inflexible," the largest and most up-to-date warship in the fleet, with her three armored cruiser consorts, the Drake ' "Duke of Edinburgh,' and "Duke of Argyll Following these were the quaint wooden training ship Portsmouth' and the Dutch protected cruiser 'Utrecht' which was *anchored in the position of honor opposite the* water gate at 110th Street where the official reception of the 'Half Moon" and 'Clermont" took place Then came the four armored cruisers 'Victoria Luise" 'Hertha" Dresden ' and Bremen representing Germany Astern of these followed what in some respects was the most imposing of the foreign display namely the first-class battleships 'Justice," "Verité' and Liberté, flying the flag of France Astern of these were the protected cruisers "Etna' and Etruria of Italy the training ship Presidente Sarmiento of the Argentine Republic the gunboat Morales' of Mexico, the U S gunboat Newport" with the President's yacht 'Mayflower' forming the last ship of the line.

THE "CONNECTICUT" "JUSTICE," AND "INFLEXIBLE'

—A COMPARISON

Of the many navies represented at the Celebration there were three which contained fighting ships of sufficient powers of offense and defense to be placed in the first line of battle namely the French British and our own It is impossible within the limits of the present paper to discuss in detail the various units which made up this nine-mile line of warships with which most of which the readers of the SCIENTIFIC AMERICAN have already been made familiar We will therefore take the three flagships the battleship Connecticut' of the United States navy the battleship Justice of the French navy and the Dreadnought' cruiser "Inflexible' of the British navy and compare their fighting power under those conditions of long range fighting under which, we are told modern battleship engagements will be fought

The theory upon which the latest battleships of our own and modern navies are being designed and according to which the crews are now being instructed in target and battle practice, is based upon the belief that future engagements will be fought at extremely long ranges probably of five miles and over Now the most accurate gun and the one that can inflict greatest punishment at long ranges is the big gun and the bigger the gun the more accurate and deadly the fire It is in this fact that we find the explanation of the modern 'Dreadnought which is armed entirely in its *main* battery with the 12 inch gun the exception being the German navy which makes use of an 11 inch piece Now the determination of the range at which a battle shall be fought lies with the ship which possesses the greatest speed for if the enemy should attempt to close in the faster ship is always able to draw away On the other hand if the enemy should wish to increase the range or draw out of the fight altogether the faster vessel can still maintain the range and place herself on whatever

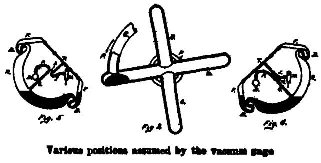
A NOVEL AIR PUMP AND VACUUM GAGE.

BY THE BERLIN CORRESPONDENT OF THE SCIENTIFIC AMERICAN.

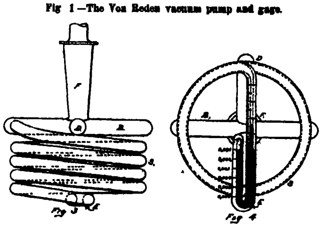
The most indispensable auxiliary of the physicist intent upon investigating those mysterious radiations the study of which is becoming more and more important is doubtless the air pump. For that reason many scientists and engineers have endeavored to improve the existing types of air pumps and have designed novel systems. One of the most interesting is that invented by Dr. Von Reden, of Fransburg, near Hanover

This is a mercury pump, the design of which will be most easily understood by reference to Figs. 5 and 6 The pump consists of a tube filled one-half with mercury, as indicated by the shaded portions. This tube is provided at its two ends with S-shaped tubes *B* and at its middle with a straight tube *C* The S-shaped tubes are connected on both sides to widened portions *F*, connected by rubber tubing with a T-shaped tube and thence by tube *I* with a water supply *W* The straight tube *C* and the bulb *D* to be exhausted are connected by a rubber tube *P* The entire apparatus turns round a pivot *A*.



Various positions assumed by the vacuum gage

Fig 1.—The Von Reden vacuum pump and gage.



Spiral glass tube attached to two cross tubes.

A NOVEL AIR PUMP AND VACUUM GAGE

After having produced a preliminary vacuum (of about 20 millimeters of mercury) in the bulb *D*, and the apparatus, by means of the water pump *W*, the apparatus is oscillated from the position represented in Fig. 5 to that of Fig. 6 and back. The mercury remaining in the S-shaped tubes *B* acts as a pressure valve, and prevents the air in the enlarged portions *F* from returning to the tubes *R*. On the other hand, the air entering from the bulbs *D* in both positions through *C* is driven by the mercury [illegible] of the apparatus through the [illegible] hand S-shaped tubes respectively, in order to be [illegible]tually discharged by the water pump. The [illegible]ing tube *R*, which, owing to its [illegible], would [illegible] very efficient, is advantageously replaced by a [illegible]tion consisting of ground-glass joints in the shape of perforated glass balls, fitting tightly in the [illegible] polished hemispherical cap, as shown in a halftone illustration, Fig. 1. In order to connect the ball with the cap, metallic springs may be employed.

Fig. 1 represents to the right a turbine belted to a pulley, which oscillates the tube by means of gearing and a crank mechanism. The glass ball joints lead to the spiral vacuum gage and the joint provides a connection with the bulb to be exhausted. A short-arm manometer is mounted below the bulb.

The pump above described can exhaust within three minutes a bulb of about 500 cubic centimeters capacity (a preliminary vacuum having been previously obtained by means of a water pump) to 1/100 of a millimeter of mercury, in four minutes, to 1/1000; in five minutes, to 1/10,000, and in thirteen minutes, to 1/100,000 millimeter of mercury, the lower handle being turned at the speed of six revolutions per minute. All the air should be expelled *from the two vacua F*, in order to obtain the vacuum last named. This is effected when the pump has been given its maximum inclination by means of the mercury, which on entering the apparatus throws back any residual air through the cocks *H* and *H'*, closed rapidly after the tube *R* has been kept oscillating for seven minutes. The pump is stopped only for a very short time.

The vacuum gage represented in Figs. 2, 3, and 4 consists of a spiral glass tube attached to two cross tubes (Fig. 3) The left-hand tube *B* incloses a small amount of mercury, and the cross tubes *B*, *D*, *O* are mounted on a standard ground-glass joint, the conical angle of which is accurately given

By turning the spiral round on the axis of the joint *G* in the direction of the arrow *P* (Fig. 2) the small amount of mercury represented at the left of Fig. 3 is made to enter the spiral, there compressing the exhausted air, until after a number of revolutions it enters the U-shaped tube *E* of Fig. 4, in order there to occupy the position marked. The left-hand arm of the U-tube is so graduated that the divisions *0 001, 0 002, etc., to 0 006*, limit 1/1000, 2/1000 etc, to 6/1000 of the total capacity of the U-shaped tube and of the spiral in the upper portion of the capillary tube. The right arm of the U-shaped tube is graduated to millimeters. In the present case, the exhausted air of the spiral is compressed as far as the division 0 001, that is, to 1/1000 of its previous volume, in the right arm of the tube, the mercury takes up a position 16 millimeters higher As, however, the atmospheric pressure in the bulb to be exhausted is 1/1000 of the pressure read on the gage, its value has accurately been 16/1000 millimeter

The spiral gage will indicate vacua up to 1/10,000 millimeter The only distinctive feature of the one used in measuring a vacuum of 1/100,000 millimeter is its being provided with a longer spiral and thinner U-shaped tube.

◆

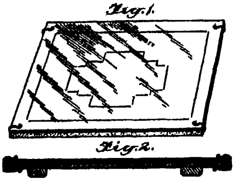
According to a consular report dealing with the trade of Chinkiang, it is proposed to build a railway from Kuachou, at the mouth of the Grand Canal, to Tsingkiangp'u and Hsüchoufou, and thence joining the Peking-Hankow line via K'aifêngfu. This line has been surveyed, and the money is being asked for among Chinese merchants. The enterprise, the report states, is to be purely a "people's undertaking." The Chinkiang-Hsüchoufou-K'aifêngfu portion is to be laid first, as the canal provides a temporary transport for goods from Tsingkiangp'u southward, and therefore this portion is not so pressing. The line is to be finished in four or five years. If the Tientsin-Pukow line gets into working order first, a great deal of the trade of Chinkiang must go to Nanking, and may never be recovered But although the future prosperity of this port would seem to depend upon the new line in question being ahead of the Tientsin-Pukow line, the wealthy merchants of Chinkiang and Yangchow and other places seem still reluctant to subscribe the necessary capital, nor will they consent to a foreign loan, however favorable in terms. It was hoped that this being a "people's line"—the Tientsin-Pukow line being official—would commend itself to the merchants [illegible] but the reason for want of support is to be [illegible] the want of confidence [illegible] placed in the [illegible]

Handy Man's Workshop

SIMPLE BLUE-PRINTING FRAME.

BY C. L. SWEENY

For those desiring to make a few small blue prints, and having no regular printing frame, the following may prove useful.



SIMPLE BLUE-PRINTING FRAME.

Secure a piece of ordinary window glass, somewhat larger than the largest blue print desired. If a piece the same size as your drawing board can be secured, it will be very convenient. Bind the edges of the glass with adhesive tape, to prevent scratching the tracing or hands. Cover the drawing board with felt or other heavy cloth, drawing the covering over the edges and fastening with thumb tacks. Make four clips, as shown in the accompanying illustration using thin spring brass or wire The exact size of clips depends on the thickness of board and glass.

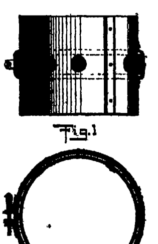
In use the sensitized paper, which can be obtained from dealers in photo supplies, is laid on the felt, coated side up, the tracing to be copied is placed in position and covered by glass, which must be clean then the clips which hold the whole in position are slipped on at the corners.

◆

THERMOSTATIC REGULATOR FOR SMOKE PIPES.

BY R. A. JOHNS.

The accompanying illustration shows a simple way in which to make a thermostatic regulator that will automatically open passages in the smoke pipe, to admit cold air, thus checking the draft of the furnace, and eventually cooling off the fire. The regulator should be placed as near the furnace as possible. Fig. 1 shows a sectional side elevation of the thermostatic regulator, and Fig. 2 a horizontal section of same In a short piece of pipe, say about 6 inches long, a number of openings are made These openings are covered with the thermostatic band, which is made as follows: A ring about 2 inches wide, and about 1 inch larger in diameter than the pipe, is made of galvanized iron. The edges are turned down by hammering, as shown in Fig. 1. These turned-down edges are fitted closely to the pipe. In the recess thus formed, a strip of brass or preferably copper is fitted and riveted very closely, say about 1 inch apart, [illegible]



REGULATOR FOR SMOKE PIPES.

To the above-mentioned galvanized ring, opposite the joint, small lugs may be provided for the purpose of fastening same to the pipe. The ring is now cut at the joint, and the ends turned in and fitted closely to the pipe. Two small lugs are riveted to these ends of the ring, with holes to receive a small stove-bolt. Between the head of this bolt and the lug on one side, place a stiff coil spring. This serves the purpose of regulating the tension of the ring so as to make it more or less sensitive to heat.

As the fire gets too hot, the copper expands more than the iron ring, causing it to move away from the pipe, and cold air from the outside will pass between this ring and the pipe into the holes of same, thereby checking the draft to the furnace, and preventing it from over-heating.

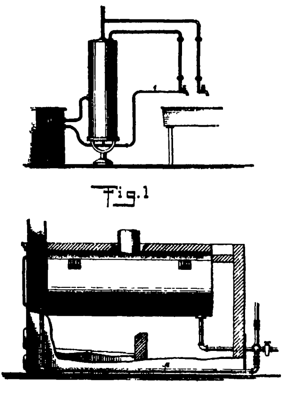
Under normal conditions, of course the spring does not open, but only under excessive heat, then it will stay open until the furnace cools off.

◆

CIRCULATING PIPE FOR HOT-WATER FAUCETS.

BY J. A. [illegible]

In turning on a hot-water faucet, it is always necessary to let the water run for some time before it gets hot. The cause of this is that the water standing in the pipe soon cools off, right up to the boiler owing to the fact that there is no circulation in same and of course a great deal of water is wasted It is an easy matter to overcome this by connecting the back of the faucet to the bottom of the boiler with a small pipe A, shown in the accompanying drawing, Fig. 1.



CIRCULATING PIPE FOR HOT WATER FAUCETS.

It is now evident that as soon as the hot water in the supply pipe cools off, owing to the change of specific gravity, it will pass downward into the circulation pipe and back to the boiler, and of course a fresh supply of hot water will flow constantly from the boiler to the faucet, and will keep up as long as there is a difference in temperature at the top and bottom of the boiler

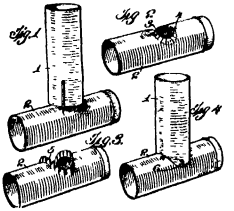
This also holds good in a steam boiler Fig 2 shows an ordinary horizontal tubular boiler Most of these boilers are fed through the blow-off pipe. This pipe is considered a weak part of the boiler, owing to the fact that the boiler is not fed constantly, but at intervals. Therefore these pipes are always required to be covered with asbestos, and sometimes protected from the hot gases by a brick wall If the boiler were fed constantly, that is to say if there were a circulation of water in this pipe at all times, the gases would have little effect on same As soon as the feed water is shut off, or rather between the intervals of feeding, this pipe is full of water which cannot circulate, and is liable to be overheated and burn To overcome this, a circulating pipe A is connected inside the blow-off cock to some part of the boiler say to the lower part of the front end A check valve may be inserted into the line, to prevent the feed water passing through the same. This pipe will at all times establish a circulation in the blow-off pipe, and eliminate all danger of being burned out.

HOW TO CONNECT STOVE PIPES.

BY E G L.

The man who desires to connect two stove pipes together and has not the tools ordinarily used for this purpose can do the work as follows

Place one end of pipe 1 against the side of the pipe 2 at the point where it is to be connected With pencil flat against the side of pipe 1, as in Fig. 1 trace off the curve on pipe 2 Leaving about 1 inch margin, cut out a disk 3 slit the margin back to the line as at 4, and turn up the tangs 5 Force the end of pipe 1 through the opening, and trace off the curve of pipe 2 Withdraw pipe 1, and cut off the end as marked. Now fit the pipe 1 into place with the tangs 5 on the inside and bend the tangs up to a tight fit. If carefully executed the joint will be sufficiently tight for all purposes



SIMPLE METHOD OF CONNECTING STOVE PIPES.

To hold the pipes rigidly together, punch small holes through the opposite sides with a sharp punch and put in a piece of stiff wire 6 Bend the ends of the wire on the outside The wire should pass through the tangs on the inside

◆

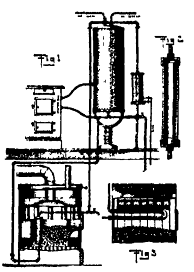
HOT-WATER CONNECTION FOR KITCHEN BOILERS.

BY JOHN B. ALLEN

In houses where the cooking is done exclusively by gas and with no fire in the kitchen range in the winter the question of having hot water in the kitchen boiler has been quite a problem in many a household especially as it is very expensive to heat this water by gas.

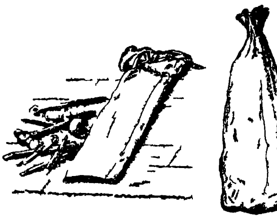
One solution of the problem is to connect the heating apparatus in the cellar with the kitchen boiler and if this be done properly there will be an ample supply of hot water at all times in fact more than needed in extreme cold weather, besides keeping the kitchen warm in the absence of any other source of heating Of course a steam or hot water radiator placed in the coldest part of the kitchen will improve conditions in severe weather

It must be understood that it takes a little more coal to run the heating apparatus although some contend that it does not Fig 1 shows a steam boiler in the cellar connected up with the kitchen boiler, also a separate gas heater for use in the summer It will be noticed that there are three independent circulations for the water, which will not interfere with each other—the circulation from the kitchen range, the one from the furnace and the other from the gas heater The connection from the furnace steam or hot water heater in the cellar or basement may of course be varied according to local conditions The accompanying illustration shows two good and reliable ways of making the connection Assume that the kitchen range is connected to the boiler in the usual way, then the connection with the furnace is made



CONNECTING THE KITCHEN BOILER TO THE FURNACE.

as follows Unscrew the hot-water connection on top of the boiler and insert a street cross if this cannot be obtained two street tees will answer the purpose. Then replace the hot water connection in this cross as before From one of the side outlets of this cross run a pipe line to the furnace and from the other to the gas heater It is well to start and finish the lines with a union as it is then an easy matter to disconnect them in case the kitchen boiler gives out or any repairs are needed The line from the boiler is run from top of same into the furnace thence down through the fire pot and grate in such a manner that it does not interfere with the proper working of the latter Thence through the side of the ash pit and up to the bottom of the kitchen boiler It is now evident that as the water in the heating pipe inside the furnace is heated it rises and fills the top of the boiler forcing the cold water out at the bottom



HOW TO CONVERT A PAIR OF OVERALLS INTO A TOOL BAG

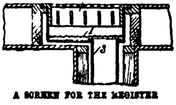
Fig 2 shows a cross section of the heating pipe inside the furnace It consists of a short piece (say 4 inches) of extra heavy black pipe threaded at each end to receive reducing caps which connect with the pipe line Inside this pipe is another 1½ inches in diameter which leaves only a small space for the water to circulate in that is to say the water is spread out in a very thin sheet which very easily heats Three small sections on top and bottom of this pipe about ⅛ inch wide are turned outward so as to fit the inside diameter of the outside pipe and thereby keep it central Outside the furnace is placed a faucet or stopcock so that the sediment may be drawn off which should be done at least once a week

Fig 3 shows the other arrangement of a heating pipe inside a sectional boiler In the back of the boiler over the fire line drill two holes about 8 inches above each other into which insert the pipes about 2 inches in diameter reaching nearly across the entire fire space Connect the same with a return ell or make it up with ordinary pipe fittings At the outside of the boiler reduce these pipes to the regular size used for the pipe line which is usually ¾ inch in diameter Attach a faucet to the lower one and connect it to the bottom and the higher one to the top of the kitchen boiler Care should be taken in running the hot water pipe from the boiler not to trap it that is to say not to let it drop on the horizontal run but rather give it as much of a rise as possible If the run from the furnace to the boiler is very long the hot water pipe may be covered with asbestos or the like A stopcock may be put in either or both lines so that the water can be shut off in case of repair The gas heater is connected at the top and bottom to the top and bottom respectively of the boiler

A SCREEN FOR THE REGISTER

BY J A BROPHY

A simple and very effective means for preventing articles dropped on the floor from falling down the hot air pipes is shown in the accompanying illustration Cut a piece of wire mosquito netting 1 the size of the floor opening By lifting out the floor register 2 the netting an be placed over the opening in the hot air pipe 3 as shown Better still bend a piece of stiff wire to the shape of floor opening and after turning the edges of netting over this frame sew the netting to the frame with fine wire Galvanized wire netting is preferable to the painted netting The writer has been able by this method to reclaim several articles of value that had dropped into a floor register



A SCREEN FOR THE REGISTER

THE BOILER MAKER'S TOOL BAG

BY A F [illegible]

When the boiler maker gets a rush order for repairing a boiler he gets busy Quickly converting his overalls into a tool bag he drops in half a dozen chisels expander hammer etc and then he is ready for action In making the bag he places the overalls full length on the floor folds one leg up and lays it on the seat of the overalls then rolls the two very tightly together criss-crosses the suspenders and ties them on the part which appears in illustration. He then puts his hand inside the leg left full length and grasps the roll and turns the whole thing inside out This completes the bag which is ready to receive the tools which of course, come against the outside of the overalls leaving the side that comes next to his garments as clean as ever

COATING ROOFS WHITE TO REPEL HEAT RAYS

BY A. S JARMAN

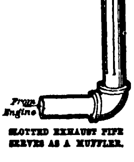
The almost general practice of painting the metal covering of the roofs of houses with the red or chocolate-colored oxide of iron is one of the causes of the insufferably high temperature of top rooms or attics during the summer months Although good as a covering for metal this paint because of its color absorbs the heat rays and conducts the heat to the interior The roof-covering material is not always metal If tar paper or tar felt and gravel have been used no kind of white paint will retain its color upon them If the covering is zinc this metal is apt to prevent the adherence of paint particularly when new Although white paint made with oil and driers can be used upon a roof previously covered with chocolate-colored paint another material must be used for a tar and gravel roof To secure a thoroughly adhesive coating upon new zinc brush over the metal the following mixture Sulphate of copper two ounces chloride of copper two ounces salammoniac two ounces water one gallon When the salts have become dissolved add two ounces of spirit of salt (common hydrochloric acid) Allow this to dry upon the zinc for about twenty four hours when it will be found that any kind of oil paint will adhere perfectly to the zinc

For a tar roof use a freshly made mixture of lime wash moderately thick and hot Two coats of this will adhere firmly to the tar and retain its white color as well as becoming very hard and resisting rain without washing off If the lime mixture has become cold the hardening property will be lost In that case to every pailful add a double handful of common salt Stir in well until dissolved This will revive the hardening quality The interior of the rooms with roofs painted or lime washed as above will be found from ten to twelve degrees lower in temperature

A MUFFLER FOR GAS ENGINES.

BY A FRED P MOR AN

The handy man who has a gasoline engine in his shop and which exhausts outside into the atmosphere may silence that disturber of the peace somewhat in the manner shown in the accompanying illustration It removes the sharp penetrating quality of the noise without causing any back pressure The end of the exhaust pipe which must be vertical in order to prevent clattering of the segments is split into eight parts by means of longitudinal cuts made with a hack saw The cuts should extend for three or four feet in the pipe



SLOTTED EXHAUST PIPE SERVES AS A MUFFLER.

TO PREVENT COAL GAS

BY L. G HANDY

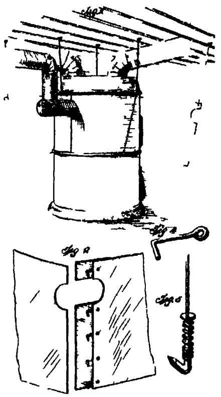
The extremely objectionable presence of coal gas in a furnace-heated house is really a simple thing to prevent. It is due of course to leaks in the air ducts through which the gas generated in the furnace enters and mixes with the fresh air that passes to the rooms above To gain access to the interior of the furnace so as to stop the leaks may appear to be a task quite beyond the average amateur's capabilities but the accompanying drawings show how the writer succeeded in doing the trick in a simple way

The top of the furnace carrying the heating pipes rested upon a cast iron ring and it was a simple matter to raise the whole thing bodily by the arrangement shown Three strong hooks were made out of large nails and under the head of each a piece of stout wire was fastened. The hooks were slipped under the iron ring. The ring was raised and the wires wound upon heavy nails driven into the beams overhead.

A 1-inch lift was sufficient and did not interfere with the heating pipes in any way but relieved all weight from the main band of the furnace and left it free to be laid open This was done with a pair of tinner's shears. The band was simply slit at the back where the heavy dotted line appears on Fig. 1 The two ends were spread apart and temporarily supported by wires to the rafters The entire interior of the air box was now accessible

Several open cracks were found Through these the gases of combustion had passed freely into the fresh-air compartment and thence to the rooms above A can of asbestos cement was obtained from a hardware dealer All surplus rust was scraped off from around the cracks with an old knife and the cement was applied freely Care was taken to squeeze enough into the cracks to insure a good hold All cracks were treated in this way and the important part of the job was finished

To reconnect the ends of the band five small holes were punched an inch from each of the two edges and exactly opposite each other From a piece of heavy iron wire five hooks were bent to the form shown in Fig. 4 These hooks each measured 2 inches from the center of the eye to the band A strip of galvanized sheet iron about 8 inches wide was punched with holes to correspond to those in one end of the band Small bolts about ⅜ inch long were used to bind all firmly together The free ends of the hooks were now passed through the holes in the opposite end of the band and bent down The strip of sheet metal on the inside formed an effective seal as clearly shown by the section Fig 3



METHOD OF REPAIRING A LEAK IN THE AIR DRUM OF A FURNACE

The band being closed the top was now lowered and the furnace was ready for use The whole job consumed slightly over three hours

The cement may need to be removed next year and to facilitate this task of the future the hooks were conveniently looped up into the rafters The back may be readily reopened by bending up the ends of the hooks and to repeat the work should not take more than an hour

Since this job was completed my fire has been made three times without the slightest trace of smoke or gas in the house

◆

In the Revue de Métallurgie Le Châtelier advocates autogenous welding for the repairing of marine boilers Referring to the important work that has been done especially in Germany in the welding of fireboxes to boilers by the aid of water gas he expresses the conviction that the same work could be done better by the autogenous process A large French shipbuilding company is employing the process in order to dispense with riveted joints in the parts of boilers that are exposed to fire heat and in one case it is stated the bracket supporting the grate of a boiler has been replaced by a fitting welded to the metal of the grate and of the fire-box

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

HOOK AND EYE.—C. S. LICHTENSTEIN, New York, N. Y. The more particular purpose of the invention is to improve the construction of both the hook and the eye for the purpose of improving the locking connection therebetween, so as to render the hook and eye rigid relatively to each other when in position on a garment.

Electrical Devices.

AUTOMATIC TEMPERATURE-INDICATOR.—W. B. CAMPBELL, Chester, S. C. The invention relates to devices for automatically indicating a predetermined temperature. It provides a temperature indicating device whose operating parts consist of metal and which is not subject to the danger of breakage like the thermostats which have the common glass tube filled with mercury.

KNOCKDOWN ARMATURE.—B. W. PERRY, New York, N. Y. This armature is mounted in a field core within permanent magnets, and gives a high potential current of unusually steady character with a low number of revolutions. It is in no danger of burning out its coil at high speed, and consequently it needs no governing or protecting device. Its capacity can be changed by the removal of the single screw and substitution of another coil of any size of wire.

Of Interest to Farmers.

CULTIVATOR.—N. TRIPP, Grand Rapids, Mich. This cultivator pulverizes the soil and whips the dirt from the roots of weeds, etc. The drum has spring digging teeth which incline oppositely to the revolution of the drum whereby they will be lifted rapidly from the ground on reaching a vertical position. The motor for driving the drum is carried on a wheel supported bed, and the drum is journaled in a frame which is pivoted at its front to move vertically relatively to the bed when raising the cultivator above, and lowering it to the ground.

RIDDLE FOR ROOT EXTRACTORS.—D. G. PATTERSON, Addington, Okla. The invention is especially adapted for use in machines for extraction of Johnson grass which propagates by means of seed roots which make a very rapid growth forming a mat in the soil so that it becomes impossible to cultivate any crop therein.

HYGROMETER FOR INCUBATORS.—G. H. LEE, Omaha, Neb. More particularly the invention relates to hygrometers known as "wet bulb" hygrometers, and it provides means for holding the evaporating fluid around the bulb. The invention also resides in the scale of the barometer which especially adapts it for use in an incubator.

STRAW AND MANURE SPREADER.—W. G. DERWILER and J. E. LIEBHAUSER, St. John, Kan. The principal objects here are to provide a mechanism for distributing the materials being handled, by power applied through the carrying wheels of the vehicles, to provide means for feeding the material being handled to the distributing members and to provide an operating construction free in operation.

Of General Interest.

MAIL-BOX AND LETTER CARRIER'S POUCH.—L. VISSAI, Jersey City, N. J. The box and the pouch are adapted to be connected with each other at their closed bottoms which latter are then capable of opening into the pouch, to allow the contents of the box to drop into the pouch, the latter on being disconnected from the mail box causing an automatic closing and locking of the bottoms of the box and pouch.

LOCKING DEVICE FOR UMBRELLAS AND THE LIKE.—W. L. SPANNING and G. B. PRINS, Jacksonville, Fla. Means provide for locking the runner sleeve and attached stretcher rods of an umbrella or parasol in closed adjustment on the umbrella stick, the means embodying a locking slide bar and a permutation lock mounted on the stick, comprising a plurality of cup-shaped rings having indicating characters thereon, the rings by adjustment controlling the sliding movement of the slide bar for locking or releasing the runner sleeve.

AUTOMATIC PIANO.—H. MAYER, New York, N. Y. The aim of this inventor is to provide a new and improved automatic piano having a simple and effective connection between the pneumatic and the keys for playing the piano automatically and for allowing playing the keys by hand.

REMOVABLE CALK.—G. S. MEYER, Newburgh, N. Y. The principal object of the present invention is to connect the calks which extend transversely of the under side of the shoe more firmly to the outer member which encircles the hoof, and to provide for the relative movement of the opposite halves of both the inner and outer connecting members.

REMOVABLE CALK FOR HORSESHOES.—G. S. MEYER, Newburgh, N. Y. The object of the present invention is to provide means for effectively holding the calks in engagement with the shoe without the necessity for a separate member extending along the inner edge of the shoe, as is employed in Mr. Meyer's prior constructions.

HORSESHOE CALK.—G. S. MEYER, New burgh, N. Y. In the present patent the object of the inventor is to simplify the calk and reduce the cost of manufacture by forming not only the calk but the part for securing the same in place, all out of a single piece of sheet metal bent to the desired form.

REMOVABLE HORSESHOE-CALK.—G. S. MEYER, Newburgh, N. Y. This invention has reference to improvements in removable horseshoe calks, and more particularly to a special form of construction whereby the calks are held in place in respect to the shoe, but all danger of the calk-bearing members being torn off by interference is avoided.

PILE-PROTECTOR.—C. N. HUBBARD, Kamela, Ore. In this case the invention has for its purpose the provision of a suitable device for automatically applying the preservative along the length of the pile by the aid of the rise and fall of the water level, thus in tide water giving the pile four applications of the solutions daily.

ORE WASHER AND CONCENTRATOR.—A. DIEU, Medellin, Colombia. The apparatus comprises two troughs or basins one above the other, the upper one being spring supported and having an outlet for the concentrates at the center of the bottom through which the concentrates are delivered to a second trough with a quantity of water added and retreated. The bottom outlet for the first basin is automatically regulated by the weight of the material in the upper trough.

COMBINATION CENTER SQUARE.—P. H. ALLISON, Torrington, Conn. In this instance the improvement refers to measuring instruments, and the object is to provide a new and improved combination center square more especially designed for accurately determining the center of round work, for laying out angles and for use as a T-square, depth gage and scale.

DOOR CHECK AND CLOSER.—O. ANSCHÜTZ, 115 Schanzenstrasse, Hamburg, Germany. The invention pertains to liquid door checks and closers and the object is to provide means whereby the beginning, middle and end speed of the door can be regulated. When the door is opened a piston is moved by rotary movement of a crank plate which is turned by means of the usual lever arm on the free end of a spindle and the spiral spring is thereby wound up.

VALVE.—W. J. BELL, Jersey City, N. J. This valve has a stationary valve seat and a valve member resting against the same, this member being revoluble step by step always in the same direction so as to leave the parts alternately open and closed, one movement of the valve opening all of the parts and the next successive movement of the valve closing them, the next opening them again, and the next closing them again.

Hardware.

LOCK AND FASTENER.—J. ROBERTSON, Perth, Ontario, Canada. The lock includes novel locking devices and a unique controlling means for the locking devices including a bar which is arranged to slide in the lock and extends into the knobs. The sliding bar is accessible to a person grasping either knob so as to be shifted to prevent turning of the knobs in opening the door. Provision is made for disposing the parts of the locking devices to convert the lock into a night latch.

LOCK.—A. LEONARD, Ashland, Wis. The lock is such as used on doors, windows, drawers, etc. The aim is to produce a lock which can be operated without a key. It is specifically a combination lock, and in its construction it comprises a number of pins or plungers, which must be placed in a certain position before the lock can be opened.

FASTENER.—K. GREEN, Yazoo City, Miss. The improvement relates to fasteners, and more particularly to such as are adapted to be used with traces or the like and each of which consists of a hook having spring controlled locking means for engaging the nose thereof and movable in a plurality of directions.

THREAD CUTTING DIE.—L. CASTRACANE, New York, N. Y. More particularly the improvement relates to that type of die in which each die proper is provided with a plurality of cutting faces, whereby the die may be adjusted to different positions to present different faces, and be used in cutting the threads on screws or bolts of different diameter.

DRAWER PULL.—C. R. ADAMS, New Orleans, La. The invention is an improvement in bolts designed for use on drawer pulls and the like although it is capable of use in other cases where bolts are put through wood or other elastic material. The bolt is adaptable to different thicknesses of board within wide limits without affecting the finish at both the inner and outer faces of the board to which the bolt may be applied.

Heating and Lighting.

MINER'S LAMP.—A. M. VAN LIEW, Houghton, Mich. The object here is to provide a light-weight miner's lamp, which is compact in form which is adapted to burn wax or the like as an illuminant in which the combustion of the wax or other substance is complete, and which thus obviates the production of smoke and other noxious gases.

GAS SCRUBBING APPARATUS.—J. J. NIX, Los Angeles, Cal. The gas is cooled and passes into a scrubber and through compartments to wash the gas. A water seal for a pipe retards the gas on its travel to the retort and the duct, and is thus fixed, and a uniform temperature avoids local, intense and destructive heat. Successive sprays of water in the scrubber washes the gas and the latter passes by way of a pipe to the holder or to the engine or other machine.

Household Utilities.

DRAIN VALVE.—H. M. KIRBY, Wilmington, Del. The object here is to produce a valve having means for normally holding the valve wide open, the valve having such a construction as will enable the valve to be locked by a simple movement in its closed position. The valve is especially adapted for use in connection with bath tubs, wash bowls and the like.

DISPENSING RECEPTACLE.—K. C. TOLLING, Memphis, Tenn. More particularly this improvement relates to a receptacle for tooth powder, which has means for dispensing the powder at will from the container and which is provided with a chamber adapted to receive the end of the tooth brush so that the powder can be dispensed directly upon the bristles.

BOOK REST.—D. DUFF, New York, N. Y. The invention provides a rest for use on tables, desks and other supports. It is simple and durable in construction, cheap to manufacture, attractive in appearance and arranged to permit convenient and quick extension or contraction according to the books to be accommodated at the time, and to securely hold the books in position.

Machines and Mechanical Devices.

DESICCATING AND PULVERIZING APPARATUS.—V. W. MASON, JR., and G. I. ROCHELLE, New York, N. Y. The invention is designed especially for pulverizing the solid constituents of milk in converting milk into a powder or flour. The primary object is to take the pasty substance and convert it into a powder by a single operation instead of first drying the material and then pulverizing it.

ADDING AND NUMBER-LISTING MACHINE.—B. HOSKINS, Seattle, Wash. This machine may be operated to add columns of figures, and will print a list of items added and also the totals of the different columns. Such machines are used extensively in banks, counting houses and similar institutions. The invention constitutes an improvement on the machine formerly patented by Mr. Hoskins.

BELT-TIGHTENER.—G. J. WALLACE, Bridgeport, Conn., and R. DOW, Mansfield, Ohio. The tightener is designed more especially for use on polishing, buffing and like machines having the driving belt arranged within the column or hollow stand of the machine, the arrangement being such that the tightening pulley is located within the column and the actuating and setting device for the pulley is arranged outside of the column convenient to the operator to enable him to tighten the belt more or less.

DRIVING MECHANISM.—N. SMELIANSKY, New York, N. Y. In its preferred form the invention consists in combination with a driving shaft of a pulley journaled on the shaft having an extended hub portion, opposed bevel gears, one journaled on the shaft, the other on the hub portion of the pulley, an idle bevel gear intermeshing with opposed bevel gears and clutches for respectively connecting the gears to parts on which they are journaled and the pulley to the shaft.

STAMP MILL.—O. C. PURKEYPILE, Ashland, Ore. The object of the inventor is to provide means for driving the stamps or hammers in such a way that they will rotate as they strike, in this way producing a desirable grinding action which brings about a very fine reduction and uniform grinding of the ore treated.

UNIVERSAL JOINT.—D. CORCORAN, Yonkers, N. Y. The joint consists of a disk having a semi-circular flange on each of its sides, the planes of the flanges being substantially at right angles to the disk and to each other and two shafts in one of the terminals of each of which there is a semicircular slot, each of the flanges being disposed in one of the slots, there being curved slots on each flange and a pin disposed in each of the shafts through the slots respectively.

ELEVATOR.—D. CORCORAN, Yonkers, N. Y. The cage has a conical disk with spiral threads on its face, there being a series of studs in the elevator shaft on which are disposed rollers respectively, the threads meshing with the latter. The disk is secured to a shaft on the cage connected by a universal joint to a horizontal shaft having a driving pulley, an idler pulley being disposed thereover. A pulley is at the top and bottom of the shaft, a motor coupled to the latter and the former journaled in a box. The box lowers when the cage reaches predetermined elevations and means provide for raising or lowering the cage independently of outside power.

THREAD AND TAPE HOLDER.—G. W. WYSS, New York, N. Y. The invention provides an attachment which may be secured to the sewing machine table or top or any other table or factory table space and which will serve for support of a plurality of spools of thread and a plurality of rolls of tape, ribbon, seam binding, or other similar material which it is desired to sew to the article or garment, and these spools and rolls are locked against displacement so that the employee cannot misplace or intentionally carry away a partly used spool or roll.

Prime Movers and Their Accessories.

ADJUSTABLE CRANK FOR INTERNAL-COMBUSTION ENGINES.—C. J. GOTTL, Tuckahoe, N. Y. In the present patent the object of the inventor is to provide an adjustable crank for an internal combustion engine whereby the length of the stroke of the piston in the cylinder can be changed to vary the degree of compression of the charge.

Railways and Their Accessories.

DOOR.—C. W. WHITMAN, Watervliet, N. Y. This improvement in doors is especially designed to be used in connection with street railway cars and has for its purpose to automatically register the number of passengers entering and which will permit of the exit without operating the registering mechanism. The movements of the motorman on the platform will not be more restricted than when the usual type of door is employed.

LOG AND LUMBER CAR.—M. M. RUSSELL, Eau Claire, Wis. This inventor has devised and put in successful practical use an improvement comprising a novel stake socket attached to bunks formed of parallel bars preferably of railroad rails, and provided with a double chain attachment adapted to hold a stake firmly, and safely for the operator.

Pertaining to Recreation.

AMUSEMENT DEVICE.—B. HESS, New York, N. Y. Generally speaking, the invention consists in a series of sinuous undulating tracks connected to an undulating surface and which are adapted to receive a carriage which travels thereon, the carriage being adapted to carry an occupant whose feet rest on suitable supporting rollers which travel on the undulating surface.

SELF-SPINNING TOP.—O. F. FERAS, Albany, N. Y. The object of the inventor is to produce a top having means whereby the top may be set spinning without using the ordinary means for this purpose. The device comprises a holder for the top having a resilient member which is adapted to be engaged by the top and which may be twisted so that in releasing the top it will exert a spinning force.

Pertaining to Vehicles.

END-GATE FOR WAGONS.—B. M. WILHITE, Gordon, Neb. The feature here consists in the employment of angle iron reinforcing bands. The bands are in pairs and bent so as to fit closely upon the exterior surface of the end gate plate and the wings thereon. Three pairs of angle iron bands are provided and fixed in place upon the end gate and wings by rivets or bolts, one pair being located at the lower edge of the end gate and its wings, another at their upper edges and the third pair midway between the other pairs.

SLEIGH-KNEE.—H. WESLE and H. WESLE, Medford, Wis. An object here is to provide means for movably attaching the clamp to the sleigh knee proper. Another is to improve the means of fastening the sleigh knee to the runner. It is an improvement on the construction shown in a former patent granted to Messrs. Wesle.

WIND-SHIELD.—J. H. SIBLEY, Norwalk, Ohio. This invention relates to improvements in wind shields for use on vehicles and more particularly to that type of shield which is formed of a lower stationary section and an upper movable section. It involves an improved form of supporting means for holding the two sections in any desired position in respect to each other.

SPEED-INDICATOR.—C. KNOFF, New York, N. Y. An object of the invention is to provide tension means for controlling the movements of the ball governor, said means including two separate springs, one of the springs operating while the indicator is rotated at slow speed while the other spring comes into play when speed increases beyond a predetermined limit, and in connection with the springs means are provided for adjusting the tension of the springs at will.

SLEIGH-RUNNER FOR VEHICLE WHEELS.—J. KARSSEN, Holland, Mich. This invention refers to runners adapted to be detachably fastened to the wheels of a vehicle. It is an improvement on a former patent granted to Mr. Karssen. The improvement which it designs to make is to render the attachment of the runner to the wheel adjustable so as to fit wheels of various diameters and having various numbers of spokes.

LEAF-SPRING.—W. J. HARRISON, West Derby, Vt. The spring is particularly adapted to motor vehicles and is designed to arrest the rebound which the conventional spring ordinarily gives when the vehicle is in motion. This is accomplished by providing the vehicle frame with spring hangers and a spring contractable in length under the weight of the load having its opposite ends connected to the hangers.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12124) N. R. S. asks: Will you be good enough to supply me the following information? I wish to have some information as to reinforced concrete construction. One of my friends writes me a letter whose substance in asking the information is as follows: "My attention has been lately drawn to reinforced concrete construction. This method of construction is, I believe, largely adopted in America and also to some extent in England and France. I am inclined to give it a trial and construct one of my buildings entirely on that principle. I have however just heard that this construction is likely to collapse after a few years owing to the corrosion of the metal which is imbedded in the concrete in order to strengthen and support the construction. Will you get me some information on this subject which may tend to definitely dispel or confirm my doubts?" I shall be much obliged if you will send some information on the above subject, or direct me to any other reliable and authentic source. A. We can, if you desire it, give you references to articles in our paper or books on the subject confirming our opinion, but without waiting to look these up we can assure you that your friend is entirely mistaken in the supposition that metal reinforcement in concrete is corroded by any action of the cement. Neat Portland cement even in thin layers, is an effective preventive of rust. Tools have been taken out of concrete known to have been under water for four hundred years, as bright as when new. Iron rods have been partly imbedded in some experimental blocks of concrete exposed to sea air, and after the external part of the iron had entirely rusted away the imbedded part had not appreciably lost weight. Concrete to be effective in preventing rust, however, must be dense and without cracks, failures in reinforced concrete or corrosion of the inclosed metal being almost invariably traceable to bad workmanship. The concrete should be liquid enough to be tamped closely around the iron and this is especially important in cinder concrete on account of the moisture absorbed by the cinders.

(12125) P. G. asks: Will you please explain the following questions? I was in New York city some time ago, and while there I visited Coney Island. I saw a show at Luna Park, representing the fight between the 'Monitor' and Merrimac" in Hampton Roads, Va. The question is this: What gives the stereoscopic effect? When I moved my head sidewise it had the vision of distance. Of course the picture was on a curtain. Where was the machine located that projected the (moving) picture? There was no shadow of the curtain. Also, please, a description of those long red tubular lights in the post office in New York city (not the Cooper Hewitt vapor lamp). A. Without further knowledge of the picture exhibit to which you refer we can only suppose that the stereoscopic effect mentioned is caused by the sidewise position of the head either shutting off the sight of one eye or in so far straining it that the sense of distance of the screen is lost, the unconscious mental calculation by which distance is judged requiring the equal use of both eyes. We know of no mechanical attachment to a kinematograph or bioscope for producing the effect. The lantern may have been at the back of the screen and the latter wet. The red lights in the New York post office to which you refer are Moore lamps, similar in principle to the Cooper Hewitt mercury vapor lamp, i. e. the light being caused by the vibrations set up in the passage of an electric current through a partial vacuum containing a residue of rarefied gas. The gas in the Moore lamp is a secret mixture, probably containing mercury vapor and something else.

(12126) E. L. B. asks: Please state in Notes and Queries the reason limestone is used in smelting iron ore. A. Limestone is added to iron ore in the blast furnace because it is the most readily obtainable and cheapest flux. Iron ore consists generally of iron oxide mixed with a gangue or earthy matter which is most commonly siliceous. The silica is infusible by itself, but in contact with iron oxide at a high temperature combines readily into silicate of iron forming slag. To prevent the great waste of iron which would result from the combination of the gangue with the metal of the ore it is necessary to provide a material with which the silica will readily unite forming a fusible slag, substances thus added to take up the gangue of the ore and other impurities being known as fluxes. Silica being acid requires a base such as lime, and the slag formed is silicate of lime. The use of fluxes constitutes one of the most important improvements ever introduced into the manufacture of iron, making it possible to reduce the metal from enormous quantities of lean ore containing as little as 25 per cent of metallic iron, whereas it was formerly unprofitable to treat ores containing much less than 50 per cent.

NEW BOOKS, ETC.

THE LIFE OF THE UNIVERSE AS CONCEIVED BY MAN FROM THE EARLIEST AGES TO THE PRESENT TIME. By Svante Arrhenius. Translated by Dr. H. Borns. Illustrated. Two volumes. London and New York: Harper & Co., 1909. 16mo. Price, 75 cents.

The original title of this work reads in German "Die Vorstellung vom Weltgebäude im Wandel der Zeiten" from which it would seem that "Life of the Universe" hardly covers the subject matter, an impression which is furthermore borne out when it is considered that Arrhenius in this work is concerned not so much with the possibility of life on other worlds, but rather with the evolution of cosmical ideas. Dr. Borns's translation (probably made from the German of Bamberger and not from the original Swedish) is not what might be termed idiomatic. Many a Teutonism creeps in but on the whole he has given a very faithful English rendering. This latest excursion of Arrhenius's into the field of astronomy is practically without a counterpart in astronomical literature. The histories of astronomy written by Delambre and by Berry are chronologies with critical comments rather than attempts at explaining the evolution of modern astronomical conceptions. Arrhenius traces the evolution of astronomical thought from the cosmogony of primitive races through the creation myths of the ancients, the philosophic systems of antiquity and the more scientific speculations of Copernicus and Kepler, until he arrives at the Laplacean nebular hypothesis and its modifications. If there is any truth in Haeckel's dictum that a true understanding of a science can be acquired only by a study of its evolution, then Arrhenius's book may be regarded as one of the most admirable astronomies ever written.

HYDROELECTRIC DEVELOPMENTS AND ENGINEERING. A Practical and Theoretical Treatise on the Development, Design, Construction, Equipment, and Operation of Hydroelectric Transmission Plants. By Frank Koester, Consulting Engineer, Assoc. Mem. Am. Inst. E. E., Member Society German Engineers (Berlin). With 500 illustrations. New York: D. Van Nostrand Company. 4to., pp. 454. Price, $5 net.

In writing this volume it was the author's intention to present a comprehensive survey of the most advanced European and American practice in hydraulic engineering. In furtherance of that end he has given an admirable discussion of air shafts and equalizing chambers in connection with pressure tunnels, seamless-welded flangeless, telescoping penstocks to facilitate shipment and to eliminate expansion joints, siphon systems, impulse wheels with draft tubes and movable water-saving nozzles, compound turbines on a single shaft, the discharge of one being the supply of the other, rapid and complete turbine tests, thirty thousand volt generators and efficient devices for protecting them against lightning, novel combinations of single and three-phase generators, wagon-panel switchboard systems, segregation and decentralization of switchboards, continuous water-flow grounders and horn gaps with micrometric setting, and two-legged transmission towers and line-crossing protection. Inasmuch as it is not the object of the engineer as a designer of hydroelectric developments to design any particular machine, such as a turbine, generator, transformer, and the like, but to provide by selection, from the different makes, an assemblage of machines and devices, each designed to perform its particular function in the most economical manner, this volume may be regarded as a handbook which will enable him to have machines properly combined for the purpose of generating and transmitting electric current from water power on a satisfactory commercial basis.

AS OTHERS SEE US. By John Graham Brooks. New York: The Macmillan Company, 1909. 8vo., 13 ill. Price, cloth, $1.75.

There are few of us who can fail to profit by a perusal of this "study of progress"—such is the author's secondary title. The author explains that he began the study by chancing, while on a journey, upon a century old volume of the criticisms of America by an early traveler, which with all its limitations and errors, so much relieved the monotony of his own travels by observation of change and development since the days of the critic, that he determined to let some foreign critic be his guide on all his later journeys. The result is a painstaking comparison of practically all that has been written of America by visitors from abroad, and the extent to which they consider us worth recording may be judged from the excellent bibliography at the end of the book comprising some hundred volumes. Nothing could be more admirable than the persistent good nature with which the author refuses to be annoyed by the occasionally insulting comments of foreign visitors when their observations are based on ignorance or prejudice, except his candid sincerity in refusing to accept from them exorbitant praise when [illegible] [illegible]. [illegible] events also [illegible] many a [illegible] vituperated as unjust or prejudiced [illegible] been just and impartial. The author's [illegible] is lucid and dignified, and in spite of the fragmentary nature of the subject, the book has more sustained interest than many a work of fiction with a continuous story.

OCEAN AND INLAND WATER TRANSPORTATION. By Emory R. Johnson, Ph.D. New York: D. Appleton & Co., 1909. 12mo., 395 pp. Price, $1.50 net.

Some months ago it gave us great pleasure to review Dr. Johnson's "American Railroad Transportation," a most fascinating and authoritative book, which we enjoyed reading from cover to cover. When the attention of the whole country is devoted to water transportation, particularly inland waters, any book which deals with such transportation is of great interest. It therefore gives us great pleasure to make a brief mention of Dr. Johnson's later volume, which is no less complete in itself than the work relating to railroads. It is a practical and exhaustive treatise on ocean and inland water as a means of transportation, its physical and economic limits, cost, tonnage, and location. The book contains interesting illustrations and valuable statistics, which gives the reader exactly the information for which he is searching. The book is a most readable one, and is an authoritative work on the subject.

INDIA, ITS LIFE AND THOUGHT. By Dr. J. P. Jones. New York: The Macmillan Company, 1909. 8vo., 375 pp., fully illustrated with photographs. Price, $2.50.

While the present unrest and political ferment in India are so much before the public the present work has an especial interest. The author's point of view is singularly sympathetic and unprejudiced, and while his book has no deliberate political aim and attempts to solve no vexed questions, it sheds a great deal of light upon the complexity of the problem of British government in India. Dr. Jones's experience of India has been that of a Christian missionary and, since his attitude is affected by that capacity, his feeling treatment of his subject is remarkably free from religious prejudice. The book is as attractive to the dilettante mental traveler as it is valuable to the ethnological or political student, and is yet adaptable to summer reading, being as interesting wherever "dipped into" as to the continuous reader. It is admirably illustrated with fine photographs, the subjects including, of course, the peerless Taj Mahal and many other less known but little less beautiful gems of Oriental art.

THE ENGINEERING INDEX FOR 1908. Compiled and published by the Engineering Magazine. New York, 1909. 437 pp., large 8vo. Cloth, $2.

The present volume entirely lives up to the reputation of its predecessors as being the most complete, if not the only, index of all engineering literature, whether included in books, technical periodicals, or the journals and proceedings of the engineering societies. This latest volume brings the investigator down to the close of 1908, while the earlier parts enable searches such as occur in patent cases and the like to be prosecuted with a minimum of cost and delay. In this book, as in the volume issued last year, the "classified" system of arranging the items is followed in place of the "strict alphabetic" order of the earlier volumes. In other words, the articles indexed are first grouped under the great divisions of engineering practice to which they belong—Civil, Mechanical, Electrical, Mining, etc.—and under these again they are sub-grouped according to the recognized special divisions of each field. This is possibly one of the greatest services the index renders to its regular users. The monthly continuation of the index, from the close of 1908, is to be found in the successive issues of the Engineering Magazine.

THE PROPER DISTRIBUTION OF EXPENSE BURDEN. By A. Hamilton Church. New York: The Engineering Magazine, 1908. 16mo., 116 pp. Price, $1.

The contents of this book, prepared originally for The Engineering Magazine, is a series of articles which at once took rank as a standard reference work on one of the most difficult questions of cost finding. A constant demand for these numbers has led to the republishing of the entire group in book form. An accurate distribution of general expense is admittedly one of the most perplexing and yet one of the most important problems with which the manufacturer must deal. The simple yet thorough analyses conducted in this volume, and the clear common sense demonstration presented will furnish a reliable guide to the solution of highly complex conditions in factory economy. The book is a most excellent one for all who are engaged in manufacturing.

THE COPPER HANDBOOK. Eighth annual edition. By Horace J. Stevens. Houghton, Mich.: Published by the compiler, 1909. 8vo., 1,500 pp.; cloth. Price, $5.

This number of the now widely known annual, which circulates in every country that has postage, more than lives up to the reputation established by its predecessors. Whereas the Copper Handbook is principally known as a complete directory of the copper mines of [illegible] and operations of each [illegible] [illegible] deal of more general interest. [illegible] is the principal chapter of [illegible] pages describing no less than [illegible] mines, [illegible] is interesting reading even to the layman, the descriptions of Calumet and Hecla, or Anaconda, for instance, being full of the romance of great industrial achievements and the conquest by American skill and enterprise of the fastnesses of nature. The book includes a glossary of mining terms and [illegible] with the most complete statistics of the industry, world's production of copper by countries and states, output of leading mines, variations of prices, share-holding and dividends of companies, etc. The compiler shows his confidence in the value of his work by sending it anywhere, charges prepaid, allowing a week's inspection and return of the book if not found acceptable.

HOW TO APPRECIATE PRINTS. By Frank Weitenkampf. New York: Moffat, Yard & Co., 1908. 12mo., 323 pp. Price, $1.50 net.

Mr. Weitenkampf is the curator of the print department of the New York Public Library, and there is no better connoisseur in the world than he. His knowledge of prints and kindred material is at the disposal of all who are in any way interested in the subject. The Lenox Library, where the prints are kept at the present time, is a Mecca for students, who are directed to the proper source of material by Mr. Weitenkampf. This qualifies him to produce a very valuable treatise, which it gives us great pleasure to review. The first chapter deals with "The Taste for Prints"; then comes a chapter on "Etchings" then one on "Line Engraving", "Mezzo-tints"; "Tint Methods", "Stipple and Other 'Dot' Methods"; "Wood Engraving", "Lithography", "The Photo-mechanical Process", "Color Prints", "Coloring"; "The Making of Prints", and "Certain Minor Information." The book is admirably written and shows a broad and catholic appreciation of the entire subject. We have not seen such a good book on prints for many years. We congratulate Mr. Weitenkampf on the production of such an excellent book.

ELECTRIC RAILWAY POWER STATIONS. By C. F. Swingle. Chicago: F. J. Drake & Co., 1909. 8vo., 720 pp., fully illustrated with photos and diagrams. Price, $2.50.

In this work the author attempts to include all that it is necessary for a central station engineer to know about boilers, mechanical stokers, steam engines, both turbine and reciprocating, gas engines of all kinds, pumps and auxiliaries of all kinds, dynamos, motors and switchboard instruments of every description. If this ambition were attained with complete success the book could hardly be so portable. It is possible that there may be central stations which include both gas engines, reciprocating steam engines and turbines, and operating engineers who desire all those machines described in one book, but we should say that any engineer who did not know as much of the contents of this book as applied to his particular work would prefer to learn it from separate books on the different subjects with space enough to treat them thoroughly. Questions and answers are interspersed through the book with no particular reference to the text, an examination on slide-valve setting appearing, for instance, at the end of a chapter on steam turbines. The illustrations are apparently taken principally from manufacturers' catalogues, and being photographs of half-tones does not add to their clearness. As a whole, at a time when more than ever it may be said that "of the making of many books there is no end," this work appears to us to fall naturally into the harmless but unnecessary class.

HINTS ON HOUSE FURNISHING. By W. Shaw Sparrow. New York: John Lane Company, 1909. 8vo.; 308 pp. Price, $3 net.

The sumptuous volume before us is filled with valuable hints on house furnishing and decoration. The plates are particularly well executed and are inserted, allowing the text to be printed on paper which is agreeable to the eye and to the fingers as well. After a general introduction which covers the subject in an admirable manner, the walls and their treatment are taken up, followed by the floors and their treatment, then come the ceiling, the windows, blinds, and curtains. A chapter on textile fabrics follows, and there is an interesting chapter on artificial heat and light. Then the furnishings of the house are treated. Crockery and porcelain are treated in the next chapter, and then comes a chapter on furniture and sanitary appliances. There are also chapters which give valuable hints on rooms for various uses. There is even a section on that much-neglected subject—garden furniture. It is a beautiful book which is worthy of a large sale.

THE AUTOBIOGRAPHY OF NATHANIEL SOUTHGATE SHALER. With a Supplementary Memoir by His Wife. With illustrations. Boston and New York: The Houghton Mifflin Company, 1909. 8vo., pp. 481. Price, $4.

In the annals of Harvard University it would be difficult, indeed, to find a man who [illegible] so far reaching an influence upon the [illegible] body at large, as well as [illegible] of the faculty [illegible]

[illegible] the late Prof. Shaler. Delightful as his wonderful personality undoubtedly was, the great public is probably more interested in his scientific attainments as a geologist. His special studies of oceanic shore lines, volcanoes, glaciology, and lunar geology are probably the works upon which his scientific reputation is most firmly seated. It is unnecessary for us to dwell upon that work here, largely because its merit was recognized in his lifetime. The autobiography before us is a charmingly written, unaffected statement of a career carefully molded from childhood, and replete with incidents that have not a little human value, inasmuch as Prof Shaler during his long life met most of the celebrities who have ever reached Cambridge and Boston, and noted his impressions of them The autobiography is a record of lifelong efforts to interpret the facts and mysteries of nature upon which Prof. Shaler so lovingly pondered.

Cooking for Two. By Jeanette M Hill Boston Little, Brown & Co, 1909 12mo., 407 pp. Price, $1.50 net

This is a handbook for young housekeepers, and is designed to give cheaply and simply and in concise form those things which are essential for the proper selection and proportion of a reasonable variety of food for a family of two. Of course, by doubling the quantity of each ingredient, enough can be prepared for four or five people The food products considered in the receipts are such as a housekeeper of average means would use on every-day occasions, with a general sprinkling of choicer articles for Sunday Menus for a week or two in each month are given The receipts are given with special attention to clearness of expression. The illustrations are particularly valuable In many cases they show the *modus operandi* and proportions, or else the raw materials and the various steps. The half tones are beautifully executed and they are well printed We have not seen any cook book for a long time which compares favorably with this one

Legal Notices

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C, in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D C

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending September 21, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Advertising device A. J Thomas	934,656
Aeroplane implement W R Turnbull	934,771
Agricultural implement, W H Rise	934,984
Alloy, antifriction E. A Tosseda	934,687
Alloy for armor plates and other uses, R. Schneider	934,697
Anchor R. Olsen	934,539
Animal trap, C. R. Shoop	934,469
Animal trap, W J Reynolds	934,685
Animal trap, D. W Solomon	934,689
Annealing box, E R. Williams	934,667
Automobile radiator, F Tudd	934,594
Automobile seat bodies, apparatus for making, M. H. Kaskian	934,619
Automobile vehicles, braking means for A. Krebs	934,547
Automobiles, valve gear for descending, H Saurer	934,762
Awning, C. R. Goodie	934,603
Balance staff pivot truing device, D L. Davies	934,429
Band cutter and feeder W Weis	934,490
Bandage, abdominal A. Patrel	934,635
Basket, fruit, J Wagner	934,485
Basket making machine, W F Barnes	934,677
Bearing, roller, J Newmann	934,631
Bed, folding, F W Abbott	934,644
Bedstead, J A. Grenier	934,607
Bicycle spring fork, C Blankenhein	934,706
Binder, loose leaf, J. C. Dawson	934,480
Binder, loose leaf, C. G. Maltby	934,469
Binder, temporary, G. D. Trussell	934,770
Binders, extensible pillar or post for loose leaf, J. S. McComb	934,746
Blowpipe, G. D. Fitzsimmons	934,514
Boiler. See Steam boiler	
Boiler, V. H. Garber	934,496
[illegible] C. L. Dahlberg	[illegible]
Book [illegible], E. E. Inman	934,690
[illegible] C. T. Kaschick	934,763
[illegible] A. G. Meisenberg	934,856

Button, fastening, R. L. Watrous	934,486
Button making machine, E. Shantz	934,940
Cabinet, barber's, R. A. Grieve	934,621
Cabinet, revolving ribbon, J W Van Patten	934,774
Cable hanger, W J Hiss, Jr.	934,609
Calculating machines with two counting mechanisms, controlling device for, R. Rein	934,756
Camera, motion picture, Depue & Jenkins	934,604
Can closure, W. J Card	934,792
Can tops, machine for feeding White & Wheeler	934,566
Cans, machine for fixing the covers of metal, W Pilastus	934,758
Car brake, C. Phillips	934,508
Car, cash entry P. M. Kling	934,818
Car convertible, C. W Benjamin	934,788
Car coupling J Timms	934,562
Car coupling C. A. Tower	934,948
Car coupling device, emergency, Turnbull & Tomlin	934,488
Car door, R. R. Jones	934,540
Car doors, loading gate for, W J Ata	934,496
Car, freight railway J G Stoller	934,579
Car, hopper, E Ullmann	934,860
Car life saving device street W DeSilva	934,509
Car placer Wilcox & Putman	934,773
Car schedule, G G Crane	934,807
Car standard, J F Fender	934,803
Car wheel, F R. Canda	934,886
Carbureter O D Munger	934,961
Carriages, sleigh runner attachment for baby, F O Kempter	934,725
Cart, hopper bottom B W Parker	934,831
Carton, folding, Galvin & Walters	934,609
Cartridge charging apparatus O. Bengtsson	934,787
Casing for balances and other instruments protecting W & A Heusser	934,686
Caster for portable tables, T R. Treiber	934,480
Cement garbage boxes, mold for forming J M Thiesen	934,477
Cemetery structure, G C. Simpson	934,704
Centrifugal switch, C. L. Kennedy	934,920
Chance controlled indicator, W G & O S. Lamb	934,550
Christmas tree holder H A Haller	934,424
Churn operating mechanism A M Johnson	934,537
Circuit breaker C. A Tucker	934,482
Circuit breaker, caloric C. C Woolworth	934,781
Cistern O M Alexander	934,647
Clamp for racks and like devices H R Langalow	934,678
Clock, E F Herschede	934,913
Cloth holding device, J F Mitcheam 934,743	934,744
Cloth rolling tube, L Canon	934,502
Clothes drier, Quinlan & Mulvaney	934,560
Clothes washer, Brooks & Crooker	934,601
Cluster socket, W C Jones	934,541
Clutch for concentric rotary parts, F H. Elliott	934,597
Clutch variable speed transmission, D. George	934,604
Coating sheet metal apparatus for, B Goldsmith	934,519
Cock, Mueller & Schuermann	934,668
Cock for mechanisms for heating liquids automatic combined gas and water Lisch & Root	934,555
Coffee grinder J. M. Brandrick	934,590
Collars, holder for wing point E. G Skinner	934,706
Compass boods, bearing taking device for A Fey	934,904
Compressed air signal R Armstrong	934,785
Concrete spring clip stirrup for reinforced W K Fellows	934,423
Condenser electric, R. Desleport	934,714
Condiment holder A Wolkenstein	934,495
Conduit, flexible, G A Luis	934,682
Conveyers, load gripping mechanism for L. C. Davidson	934,690
Conveyors, pneumatic jet for E W Rice	934,628
Cooking device C B Trescott	934,858
Corer peeler, and slicer apple W T Ross	934,840

Commutator, W. A. Dick	935,300
Compasses, L. Harris	935,497
Composing machines, galley mechanism for typographical, Pearce & Billington	935,543
Concentrator and classifier, centrifugal, F. Laist	935,311
Condenser, E. N. Woodruff	935,446
Cooler. See Water cooler	
Coop or crate, folding, F. T. Wing	935,448
Corn hanger, F. F. Swanson	935,549
Cotton choppers, caster wheel for, J. W. Garrett	935,506
Cotton grader, L. A. Greene	935,140
Cotton picker, D. M. Bailey	935,188
Cotton press, F. E. Thomas	935,438
Coupling, A. H. Harris	935,024
Crank, variable throw, G. R. Grout	935,496
Cream separator, G. N. Wolf	935,183
Culinary utensil, D. H. Coles	935,189
Cultivator, E. B. Fitzgerald	935,008
Cultivator, C. Gardner	935,487, 935,488
Cultivator, Benton & Jordan	935,578
Cultivator, disk, W. L. Clevenger	935,297
Culvert mold, Fife & Coleman	935,007
Current motor, alternating, A. C. & T. R. Bell	935,552
Curtain rod fixture, L. K. Brigham	935,557
Cushion, railway, W. Hill	935,509
Cutter guard, P. Foster	935,481
Damper regulator, Mitchell & Brawley	935,390
Davit lock, Ryan & Tanning	935,413
Dental and like instruments, rack or tray for, W. L. Smith	935,420
Dental and like tools, rack for, W. L. Smith	935,419
Die and die support, W. D. Coolidge	935,403
Dish washing device, M. Froese	935,146
Dispensing machine, P. C. Petersen	935,401
Display or show case, W. Freeman	935,100
Displaying apparatus, sample, G. E. Farles	935,302
Ditching and grading machine, W. I. Short	935,240
Door opening apparatus, automatic, L. Effenberger	935,477
Door operating means, Rogers & Vogel	935,410
Door stop, F. M. Moser	935,202
Draft appliance, W. W. Winger	935,180
Draft equalizer, F. E. Travis	935,474
Draft hook, D. P. Springer	935,423
Draft riggings, machine for testing and registering operation of, J. F. O'Connor	935,162
Draft sill, Acker & Bundy	935,449
Dredgers, excavators, etc., tooth for steam, C. E. Gardner	935,147
Drill holder, A. H. Knight	935,065
Drill support, electromagnetic, G. Doenig	935,201
Drilling machine table, A. Davis	935,470
Drilling machines, material holder for, S. P. French	935,010
Drip pan, M. C. Smyth	935,278
Dry separator, R. R. Snowden	935,421
Duplicating or printing machine, Havens & Page	935,604
Dust collector, G. Saeny	935,068
Dust through the application to roads, or road material of an aqueous emulsion of oil, preventing and laying of, W. M. Sandison, reissue	13,024
Dye, azo, Gunther & Hesse	935,018
Dye, azo, Kahn & Osenbeck	935,031
Dye, azo, Julius & Fussenegger	935,171
Dye, sulfur, J. Flachslaender	935,009
Dye vat, J. Deinet	935,600
Dye, yellow, Gunther & Hesse	935,016
Dye, yellow azo, Gunther & Hesse	935,017
Dyes and making them, pyramidone, Julius & Fussenegger	935,170
Educational device, A. C. Immer	935,256
Egg beater, F. P. Burr	935,063
Electric distribution, J. L. Creveling	934,997
Electric fixtures, outlet box for, Erickson & Bradshaw	935,097
Electric furnace, A. Reynolds	935,548
Electric light flasher, automatic, J. O. Houser	935,207
Electric light hanger, adjustable, L. Baendert	934,993
Electric outlet boxes, hanger for, A. McMurtrie	935,319
Electric shade holder, E. F. Gennert	935,012
Electric switch, J. G. Peterson	935,226
Electrode, storage battery, L. H. Flanders	935,368
Electrodes for electrolytical purposes, making durable carbon, Adolph & Pietzsch	934,988
Elevator, W. T. Long	935,378
Elevator door operating device, C. L. Grohs	935,109
Elevator gate lock, automatic, R. F. Joyce	935,607
Elevator safety brake, automatic, L. Givulinovich	935,200
End gate, C. Schallau	935,169
End gate, J. H. Harvey	935,406
Engines, device for barring over, O. B. Sargent	935,285
Engines, dynamometer thermo couple for explosion, N. M. Hopkins	935,154
Envelope, safety, E. S. Nyce	935,270
Explosive compound, F. H. Briggs	934,980
Extension table, E. L. Marston	935,608, 935,609
Fan, rotary, J. Keith	935,114
Fare indicator and register, H. E. Sayer	935,273
Fence, T. W. King	935,082
Fence stretcher, M. E. Johnson	935,070
Fence wire releasing device, F. Cummings	934,989
Fertilizer distributer, J. H. Bloom	935,579
Filling and capping apparatus, F. J. Heybach	935,503
Filter, D. W. Field	[illegible]
Filtering apparatus, D. Dyce	[illegible]
Finishing process, E. L. Haskell	[illegible]
Fire escape, W. [illegible]	[illegible]
Fire escape, M. S. Woods	[illegible]
Fire extinguishers, sprinkler head for automatic, H. K. Hopkins	[illegible]
Fire [illegible] mortar and shot therefor, [illegible], E. H. McCleod	[illegible]
Fire shield, collapsible, J. A. Dennis	[illegible]
Firearm, A. Fyrberg	935,308
Firearm, A. J. Savage	935,567
Firearm, repeating, G. S. Lewis	935,514
Firearms, recoil pad for, M. S. Parker	935,132
Fish scaling machine, A. Grub	935,058
Floor drain, G. J. Dehn	935,030
Floor scraper, F. M. Israel	935,229
Flooring and ceiling, interlocking, J. W. Piver	935,408
Flue expander, J. P. High	935,366
Flushing cistern for closet bowls, Van Sandt & Thacher	935,341
Flushing tanks, float ball for, T. Swernsen	935,488
Flying machine, A. H. Malasomma	935,099
Flying machine, W. H. Martin	935,594
Fork. See Loading fork.	
Form locking and adjusting device, E. I. Massot	935,213
Fruit washer, C. H. Hallauer	935,301
Furnaces and converters, operating blast, J. Gayley	935,028
Fuse for projectiles, safety percussion, D. J. Cartwright	935,198
Game apparatus, F. Dando	935,469
Game apparatus, T. S. Campbell	935,085
Garden implement, W. C. Dodge	935,478
Garment, bifurcated, F. F. Lewis	935,159
Garment fastener, C. H. Schmidt	935,298
Gas and air for illuminating purposes, manufacture of a mixture of, F. W. Wolff	935,444
Gas engine, J. T. Cowie	935,191
Gas generating apparatus, J. H. Stringham	935,388, 935,489
Gas generator, J. S. Loder	935,119
Gas generator, hydrocarbon, E. B. Brown	935,394
Gas, making water, C. E. White	935,344
Gasket, C. I. M. Martin	935,397
Gate, A. K. Holdeman	935,206
Gate, W. H. Clark	935,568
Gate and door, H. P. Latham	935,374
Gear case, O. W. Bandy	935,351
Gear mechanism, sliding, H. M. Russell, Jr	935,386
Gear, variable transmission, J. J. Knecht	935,024
Generators to secure constant potential, device for regulating the speed of, A. L. Parker	935,051
Glass cutting table, Green & Henry	935,014
Glove, G. C. Fried	935,011
Governor, G. H. Wilson	935,442
Grain bin, A. N. Eaton	935,096
Grain separator, G. E. Arnold	934,990
Graphite article and making same, A. M. Williamson	935,190
Grinding apparatus, tool, G. R. Riddle	935,495
Grubbing implement, L. P. Harvey	935,020
Gun with recoiling barrel, E. Olsson	935,222
Hame clip, W. A. Wilson	935,060
Hammock frame, collapsible or folding, K. L. Hyller	935,513
Hammock supporting frame, M. D. Wolf	935,445
Hand wheel, A. Hallowell	935,019
Harness attachment, I. M. Stevens	935,173
Hat frames, device for forming wire, W. M. Jameson	935,305
Hat ventilating attachment, C. A. H. Smith	935,556
Hatch cover, G. H. Tackman	935,431
Hay press, M. A. Westbrook	935,179
Headlight attachment, F. J. Pfister	935,228
Heater, T. J. Bartow	935,244
Heaters, injector for hot water, J. W. Guimont	935,015
Heel, cushion, J. Cairns	935,099
Hinge, A. D. Perkins	935,611
Hinge, cover, C. G. Bloomer, Jr	935,097
Hinge, segmental, W. Favreau	935,584
Hoe, scuffle, A. S. Knapp	935,116
Hoist, electric, A. A. C. Gear	935,383
Hook and eye, W. Ferris	935,098
Hoop projecting device, C. M. & T. Bartholomew	935,458
Horse checking device, Hobbs & Jewell	935,625
Hose construction, C. M. C. Baird	935,091
Hose coupling, G. A. Anderson	935,062
Hose coupling, instantaneous, W. J. Casey	935,547
Hot water heater, W. H. Kogle	935,117
Hub attaching device, R. G. Roulstone	935,601
Hydrant casing, J. Day	935,471
Hydrant head, irrigating, N. B. Twiford	935,566
Hydrocarbon burner, J. Stubbers	935,480
Hygienic heater, H. L. Stutts	935,581
Ice cream freezer, continuous, H. J. Gerner	935,400
Ice cutting machine, A. J. Offord	935,127
Implement frame, A. C. Dewey	935,144
Incandescent bulbs, capping machine for, T. J. Hetherington	935,508
Incubator, multiple compartment, C. E. Adair	934,996
Insect catcher, H. Stramrubach	935,428
Inverted burner, J. J. Weyer	935,241
Iron or articles cast from iron, reducing the amount of carbon in cast, W. Rubel	935,234
Ironing board, M. L. & O. Bacon	935,184
Jar closure, E. W. Pearce	935,121
Journal bearing, Heron & Deverell	935,072
Key retaining device, Guindon & Tyson	935,083
Kinematograph apparatus, driving mechanism for, C. Rosel	935,167
Lamp, electric arc, A. D. Jones	935,518
Lamp, miner's, O. M. Muller	935,210
Lamp operating mechanism, Warfield & Nicholson	935,437
Lamp suspension device, electric arc, A. Wunderlich	935,136
Lantern head, A. R. Pritchard	935,304
Lard gage extractor, T. F. Ray, Jr	935,401
Lasting machine, F. Chase	935,090
Lathe, G. W. Davis	935,148
Lathe tool holder, J. D. Ramsey	935,547
Lavatory, S. Redson	935,290
Lavatory, W. Bunting, Jr	935,621
Lawn sprinkler, W. Vossler	935,071
Lawn trimmer, Person & Uhler	935,225
Leather splitting machine, T. H. Mayo	935,533
Ledger and file combined, L. A. Hochman	935,103
Level and gage, track, C. C. Lynch	935,036
Lever, hand, R. H. Bowman	935,061
Lifting apparatus, T. M. Smith	935,170
Liquid distributing apparatus, C. Potts	935,231
Liquid meter, Speed & Wright	935,129
Liquids and gases, apparatus for effecting intimate contact of, Hervey & Blake	935,501
Loading and unloading apparatus, B. F. Miller	935,049
Loading fork, H. Pederson	935,544
Lock. See Car door lock	
Lock mechanism, M. Burch	935,004
Locomotive boiler superheater, O. W. Ott	935,224
Locomotive superheater, O. W. Ott	935,223
Looms, thin place detecting means for, H. L. Freeman	935,090
Lubricator, J. Kelly	935,260
Magnesium carbonate, producing, G. Simon	935,418
Mail bag crane and catcher, J. G. Fleenor, Jr	935,396
Mail bag delivery apparatus, J. G. Fleenor, Jr	935,395
Mail bag lock, G. I. Willett	935,257
Mail box coin holder, rural, G. E. Wemhoff	935,076
Mail box collection indicator, W. W. Day	935,191
Mail crane, railway, J. C. Adams	934,987
Manure loader, J. R. Mohan	935,391
Manure receptacle, W. H. Hunt	935,511
Marine table, J. U. Jones	935,156
Match box and cigar cutter, combined, Ross & Ward	935,411
Match box, safety, J. & W. H. Demaine	935,472
Meat skinning machine, J. O. Willifar	935,161
Medical irrigator, Pfeifer & Towles	935,327
Merry go-round, F. A. Dyson	935,008
Metal plates, apparatus for pickling and washing, G. Mesta	935,619
Metal sawing machine, C. Napier	935,386
Metallic compounds, wet method of separating, J. H. Thwaites	935,337
Milk can, jacketed, P. Larsen	[illegible]
Milking machine, W. J. Uebler	[illegible]
Milling machine, bevel gear, F. L. Weston	935,077
Milling machine, cycloidal, C. Wiebke	935,245
Mirror stand or support, adjustable, G. P. Humphries	[illegible]
Miter box, J. A. Leland	[illegible]
Mop making machine, A. Lackey	[illegible]
Motors, controlling electric, J. L. Routh	[illegible]
Music stand, M. [illegible]	[illegible]
Musical device, J. W. [illegible]	[illegible]
Napkin clasp and holder, combined, W. L. [illegible]	[illegible]
Nest egg, J. F. Ault	[illegible]
Nozzle, spray, F. A. Myers	[illegible]
Oar blade forming machine, J. [illegible]	[illegible]
Oar blade shaping machine, J. [illegible]	[illegible]
Oat sack, H. C. Hodgkins	[illegible]
Oil burner, W. A. Mast	[illegible]
Oil burning furnace, C. A. Hammel	[illegible]
Oil feed for drills, M. Galowitz	[illegible]
Oilstone holder, Budge & Castle	[illegible]
Ore screen, [illegible]	[illegible]
Outlet box, L. H. Church	[illegible]
Pan cover, frying, L. J. Buehl	[illegible]
Paper cutting device, C. Van Middlesworth	[illegible]
Paper making system, H. S. Rinker	[illegible]
Paper roll bracket, S. Wheeler	[illegible]
Paper vessel, C. F. Jenkins	[illegible]
Paper winding device, H. M. Griffin	[illegible]
Parer, ear corn, M. R. Johnson	[illegible]
Pay station, automatic, H. W. Hamlin	[illegible]
Pencil holder, J. W. Myers	[illegible]
Photographic developer, Kelly & Bentham	[illegible]
Photographic developer, W. F. C. Kelly	[illegible]
Pick, Gill & Gates	[illegible]
Picture, C. W. Saalburg	[illegible]
Pipe joint, E. B. Rust	[illegible]
Pipe line shafting, coupling clamp for, J. E. Jones	935,111
Pipe mold, R. L. Mang	[illegible]
Pipe puller and holder, S. L. Blake	[illegible]
Pitman connection, Chrysler & Kays	[illegible]
Planter, H. Smith	[illegible]
Planter, seed, C. T. Pine	[illegible]
Plectrum action, J. Robbeck	[illegible]
Plow, ditching, J. M. Cornelius	[illegible]
Plow harrow attachment, H. Seltner, Jr	[illegible]
Plow lay holder, J. J. Klein	[illegible]
Plug attachment, C. J. Klein	[illegible]
Pneumatic motor, R. A. Norling	[illegible]
Pocket knife, E. Mallon	[illegible]
Potato digger, F. Lemer	[illegible]
Powder ejector, W. W. Sands	[illegible]
Press. See Baling press	
Print developing and washing apparatus, H. C. Gawler	935,149
Printer and recorder, check, W. H. Baur	[illegible]
Printing frame, L. D. Gague	[illegible]
Printing machines, sheet delivery mechanism for, T. M. North	[illegible]
Printing plate clamp, flexible, J. White	[illegible]
Printing plate foundation, W. S. Warnock	935,078
Printing press attachment, C. Van Middlesworth	[illegible]
Printing presses, construction of reciprocating beds for cylinder, M. Rockstroh	[illegible]
Prismatic and diffusion inclosure, O. A. Mygatt	[illegible]
Propeller, lifting and driving, R. Strehlau	[illegible]
Pulverizing machine, W. K. Nix, Jr	[illegible]
Rack or holder, Hill & Gray	[illegible]
Radiator, S. D. Stauffer	[illegible]
Rafting system, log, N. O. Elfer	[illegible]
Rail, J. Keeton	[illegible]
Rail joint, J. F. McGhee	[illegible]

HOW TO MAKE AN ELECTRICAL Furnace for Amateur's Use.—The utilization of 110 volt electric circuits for small furnace work. By N Monroe Hopkins. This valuable article is accompanied by detailed working drawings on a large scale and the furnace can be made by any amateur who is versed in the use of tools. This article is contained in SCIENTIFIC AMERICAN SUPPLEMENT, No. 1182. Price 10 cents. For sale by MUNN & CO., Inc. 361 Broadway, New York City, or by any bookseller or newsdealer

FRICTION DISK DRILL
FOR LIGHT WORK.
Has These Great Advantages:
The speed can be instantly changed from 0 to 1600 without stopping or shifting belts. Power applied can be graduated to drive, with equal safety, the smallest or largest drills within its range—a wonderful economy in time and great saving in drill breakage. ☞ Send for Drill Catalogue.

Concrete
Reinforced Concrete
—AND—
Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete by Brysson Cunningham The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete

Scientific American Supplements 1567 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut Henry J Jones of the various systems of reinforcing concrete concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A. Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley Jr on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete depositing of concrete, facing concrete wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

STEREOSCOPIC MOVING PICTURES IN NATURAL COLORS.

(*Continued from page 256*)

pictures are taken and projected intermittently, the shutter both in the camera and projector being a sector having an area approximately one-seventh of the area of a circle. While the shutter is closed the film is jerked forward by an interval equal to the height of a single picture on the film. In the Friese-Greene apparatus, however, a continuous picture is secured, since the operation of the twin lenses is alternating that is to say while one is closed the other is open. Consequently although the separate films carry images intermittently recorded, the one secures those which the other lost during the short space of time its lens was closed by the shutter

In regard to the arrangement of the color filter and its manipulation a highly important development has been effected The color filters are disposed on an endless band of transparent celluloid in the order of red green, and blue. Each filter is of the same size as the cinematographic image on its film namely, ¾ inch deep by the standard width, and like the latter is perforated along its edges so that the movement of the color filter and sensitized films are synchronous and the two being kept in dead juxtaposition By reducing the thickness of the color filter medium to the infinitesimal proportions of a thin celluloid band all troubles concerning light refraction and reflection are completely overcome.

By reference to the accompanying illustration showing the interior of one side of the stereoscopic camera, its operation may be clearly understood, as well as the disposition of the color filter band Starting from the point *A*, which is a pulley, the color filter band passes to and over the jockey pulley *B* thence around the drum *C* where it picks up the unexposed sensitized film issuing from the unexposed film spool box at the top on the right, and is superimposed on the sensitized surface of the film The color filter and film are now caught with their respective edge perforations in dead register, and carried down through a guide channel *D* to the point of exposure behind the lens As the shutter is closed the oscillating twin pronged arm *E* falls and the teeth engaging with the perforations of the two superimposed films pulls them down together over the lens for a distance of three-quarters of an inch—the height of a cinematograph picture—and holds them firmly there during exposure This completed the turning of the driving handle raises the pronged oscillating arm *E* so that the films are released, and the arm rising in its travel falls and grips the films, once more jerking them down another three-quarters of an inch over the lens aperture This cycle of operations is repeated while exposures are being made, successive filters and corresponding sections of sensitized film being brought forward in this manner

As the exposed film surface and its color filter pass away from the lens they travel together over another jockey pulley and drum *F*, after which the two separate, the exposed film passing over the pulley *G* and entering the exposed film box, where it is wound on the spool in the usual manner while the color filter band travels over the pulley *H* along the base board of the camera under the guide pulley *I*, up the back of the apparatus over pulley *J* and along the top to pulley *A* and *B* to *C* where it picks up the sensitized film once more. The same cycle of operations is repeated during the period exposures are being made.

The second half of the camera is precisely the same in construction and operation as the first half. There is one important difference in the disposition of the color filter band in regard to its exposure, relatively to that in the other half of the camera. A blue instead of a red screen passes before the second lens aperture synchronously with that before the first lens. The effect is that in the course of the exposures there is a continual cutting off of the respective colors. That is to say, when red is exposed for the first lens, it is immediately succeeded by the blue in the second lens, followed in turn by green in the first lens, the latter then being cut off by the red in the second lens, then blue in the first, succeeded by green in the second lens, and so on The accompanying diagram will best illustrate how the successive cutting off of the colors is effected

Another notable point is that the inventor does not require three separate negatives taken through the red green and blue color filters respectively and then similarly superimposing their transparencies through relative color filters to secure the three-color effect. Such is the process generally followed in accordance with the Ives system of still life color photography By this last named process the film would obviously have to be three times the length of the monochrome record, in order to secure the three fundamental negatives and would need to be projected at three times the speed to secure the desired effect Mr Friese-Greene, however, has ascertained that in chromo-photography such a process is unnecessary when carried out upon his lines and that the continual cutting in and out of the colors will enable them to be blended so easily and rapidly that the brain sees the heliochromic image only

It will be realized from a study of the shutter arrangements in the accompanying illustration that each lens is insured an equal period of exposure The shutter area is exactly one-half of that of a complete circle and as one lens aperture is being cut off the other is being cut in which materially assists in the blending of the colors through their respective filters, there being an entire absence, from the eye point of view of any sharp line of demarcation The sighting and focusing of the camera follow the usual practice in such cinematographic apparatus, as does also the method of operation for taking photographs though certain improvements have been incorporated The camera itself is practically the same size as that of the single-lens instrument, everything being rendered as compact as possible

The projector follows the lines of the ordinary instrument for this purpose with the exception that there are two lenses placed side by side Here again the exposure is intermittent The two lenses are each fitted with a micrometer screw so that their angle to one another can be adjusted to a nicety and varied according to the size of picture projected, which of course is relative to the distance of the screen from the projector The facilities whereby the angle of the lenses to one another is adjusted insures that irrespective of the size of the image exact superimposition of the two pictures projected from the twin lenses is absolutely certain upon the same given area.

In the projector two similar endless color filter bands have to be used Their arrangement is very similar to that adopted in the camera and suitable devices are employed for keeping them in absolute register with the picture film It is quite impossible, therefore, for any difference in register upon the screen or confusion of color filter and its relative picture to result. Moreover, there is the same relationship in regard to the cutting in and out of the respective color filters to secure the desired blending of the colors, so as to insure in conformity with the phenomenon of visual persistence the impression of a perfect three color image being conveyed to the brain This result is also assisted by the fact that projection is really carried out at twice the usual speed, thirty-two pictures being thrown on the screen in the course of a second from the two lenses—sixteen from each. Owing to the perfect superimposition of the pictures from the

BUSINESS OPPORTUNITIES

WILL FURNISH capital for promoting good patent, franchise or public utility or other good enterprise. Must come well recommended. Address P. F. Gallagher, Prudential Building, Newark, N. J.

Inquiry No. [illegible]. Wanted to buy [illegible] for [illegible].

MANUFACTURERS, CAPITALISTS. I will sell outright or manufacture on royalty a most valuable invention. For full particulars address M. R. Schultz, Southampton, N. Y.

Inquiry No. 9014. For manufacturers of "[illegible] Electric [illegible] Sparking Plug."

A RARE OPPORTUNITY presents itself for a high class salesman to handle an article of utility needed on every store, in every home and office as well as halls and churches. [illegible] S. W. Michigan St., Chicago.

Inquiry No. 9029. Wanted the address of Worth [illegible].

PATENTS FOR SALE

FOR OUTRIGHT SALE or on royalty U. S. Patent No. [illegible], Canadian Pat. No. [illegible], dump distributor for dump grain; is needed in every elevator. For further information address J. R. Pattinson, Stafford, Kansas.

Inquiry No. 9060. For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

FOR SALE. Valuable box-shaving patent, improves quality and greatly reduces cost of manufacture. For further information and particulars, inquire Room 1109, 11 Pine Street, New York.

Inquiry No. 9066. Wanted the address of the [illegible].

FOR SALE. [illegible] top. Mechanism all hidden; [illegible] Will sell outright or on royalty. [illegible] August 17, 1915. T. N. Reed, Dallas, Tex.

Inquiry No. 9069. Wanted machines that make accordion dress plaiting by steam.

FOR SALE. A small and cheap article which can be used for home use, to be used on vases, etc. For cash or royalty. For further information address George H. Pearson, 509 Parnell Avenue, Chicago.

FOR SALE

FOR SALE.—Engine lathe, swing [illegible] in., takes [illegible] in. between centers. Complete with full set change gears [illegible] ready for use. Price only [illegible]. Address F. F. Grossman & Sons, Allentown, Pa.

Inquiry No. [illegible]. For the address of manufacturers of mortars and pestles that are used by druggists.

MISCELLANEOUS

HAIR GROWN when our Vacuum Cap is used a few minutes daily. Sent on 60 days free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 588 Barclay Block, Denver, Colo.

Inquiry No. [illegible]. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box [illegible], New York.

Inquiry No. 9000. For information regarding [illegible] made of leather or similar to the same as are [illegible].

A LIST OF [illegible] mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price [illegible]. Address Munn & Co., Inc., List Department, Box [illegible], New York.

Inquiry No. 9006. Wanted addresses of manufacturers of machinery for working orange wood and manicure sticks.

Inquiry No. 9007. Wanted the address of the manufacturers of bread or cake boxes.

Inquiry No. 9001. For the address of progressive manufacturers of fruit jars.

Inquiry No. 9010. Wanted to buy a "Rector Help-a Phone."

Inquiry No. 9012. Wanted to buy papier mache boxes in the shape of watermelons, colored to resemble melons, etc.

Inquiry No. 9011.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of diamond tipped gold [illegible] for fountain pens.

Inquiry No. 9016. Wanted, machinery necessary for an installation of a plant for refining salt by a [illegible].

Inquiry No. 9017. Wanted the address of manufacturers dealing in [illegible] board, paper or wood pulp for plaster [illegible].

Inquiry No. 9018. Wanted, the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9021.—For manufacturers of machinery for manufacturing alcohol and turpentine from sawdust.

Inquiry No. 9022. Wanted to buy a light, small motor not exceeding three pounds in weight, including everything in working order.

Inquiry No. 9023. Wanted to buy silk machines from reeling [illegible] to the final process of making [illegible].

Inquiry No. 9024. Wanted the address of parties who can [illegible] fire extinguishers of metal.

Inquiry No. 9025. Wanted address of rubber manufacturers in Germany.

Inquiry No. 9026. Wanted address of parties who make "Invar" or other metals having a low coefficient of expansion.

Inquiry No. 9027. Wanted, the address of manufacturers of small wooden articles.

Inquiry No. 9028.—Wanted, to buy a washing machine [illegible] by a coil spring motor.

Inquiry No. 9029. Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

two lenses upon the white wall [illegible] able clearness and definition are obtained the color beauty of the image being appreciably enhanced by the stereoscopic effect which is produced. As also the two pictures depict continuous motion there is an entire absence of flickering due to the shutter, the effect being practically the same as if one were resorting to the camera obscura.

In order to secure the requisite stereoscopic effect in projection the apparatus for this purpose has necessarily to be of special design. Its general characteristics are plainly shown in the accompanying photographs (Figs. 4 and 5). There is the lantern body for carrying two illuminants, one for each lens. The lenses themselves are rendered angularly adjustable by means of a micrometer screw so that in stereoscopic work the two images may be exactly superimposed upon the screen and yet at the same time rendering it feasible to use the apparatus for ordinary work by cutting one-half of the lantern out of service.

The operating mechanism, while broadly following that of the ordinary single projector, is simpler. The feed spools are carried on a common axle at the top and the films lead down to their respective lines of travel through the gateway behind each lens, subsequently being wound up on the lower spools, these working synchronously through a central spring pulley drive.

Color projection can be effected either by a revolving disk carrying three equal sized sectors of red, green and blue glass respectively, the cutting in and out of each color being precisely the same as in the camera. That is to say, while one lens is being uncovered the other is being closed, so that in reality the image from one lens is being thrown on the screen at one time instead of the two exposures being made simultaneously as in ordinary stereoscopic practice. It is the speed with which projection is made and the cutting in and out of the colors on each lens—about 5 per second—that in accordance with the peculiar law of visual persistence yields not only the natural color but also the stereoscopic effects.

Though the rotating disk is the simplest means of projection, the color effects are not technically correct nor so beautiful as are produced by the endless traveling band composed of small color screens, red, green and blue successively. This is attributable to two factors. In the first place, as the rotating disk is placed in front of the lens there is a certain distance through which uncolored light travels—that is, between the film and the color screen—and in projection there is a tendency toward jumbling of the three colors into the white light. On the other hand, when the color screen is in immediate juxtaposition with the film no white light whatever is projected.

The apparatus shown in the accompanying illustrations is applicable to either disk or endless band operation. If the band is used it is only necessary to withdraw the colored screen sectors from the revolving shutter, which is readily effected by means of clips which hold the screens in position, the three remaining opaque sectors acting as the cut-off between each successive color filter and its picture on the band. The band itself is carried over a jockey pulley and sprocket drum at the top of the projecting mechanism and carried down through the gateway with the transparent film against which it is tightly held during the instant of projection. Issuing from the gateway it passes over a lower sprocket drum and jockey pulley, where it leaves the picture film, which is wound on the spool below, the color band passing over a rigid horizontal arm shown in the illustration set at an angle of about 45 deg. so that the upward traveling part may clear the field of the lens, passing over another similar angular arm at the top which deviates it.

(Concluded on page 271)

Practical and Instructive [illegible]

AGRICULTURE.—The New Agriculture. By T. Byard Collins. 12mo. [illegible] pages. [illegible] illustrations. [illegible]

A popular outline of the many changes which are revolutionizing the methods of farming and the habits of farm life. It is one of the most practical treatises on the subject which has ever been issued.

ALCOHOL.—Industrial Alcohol. Its Manufacture and Uses. By John K. Brachvogel. 8vo. 528 pages. 107 illustrations. [illegible]

A practical treatise based on Dr. Max Maercker's Introduction to Distillation, as revised by Drs. Delbrueck and Lange, comprising raw materials, malting and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat and power production, a statistical review, and the United States law.

AMATEUR MECHANICS.—Home Mechanics for Amateurs. By George M. Hopkins. 12mo. 370 pages. 326 illustrations. $1.50

This is a thoroughly practical book by the most noted amateur experimenter in America. It appeals to the boy as well as the more mature amateur. Holidays and evenings can be profitably occupied by making useful articles for the home or in the building of small engines or motors or scientific instruments.

AMUSEMENTS.—The Scientific American Boy. By A. Russell Bond. 12mo. 317 pages. 340 illustrations. [illegible]

This is a story of outdoor boy life suggesting a large number of diversions which, aside from affording entertainment, will stimulate in boys the creative spirit. In each instance complete practical instructions are given for building the various articles.

COMPRESSED AIR.—Compressed Air. Its Production, Uses and Application. By Gardner D. Hiscox. 8vo. 665 pages. 540 illustrations. [illegible]

The most complete book on this subject. It treats on its physical and operative properties, and is written by an expert. Taken as a whole it might be called an encyclopedia of compressed air.

DIES.—Their Construction and Use for the Modern Working of Sheet Metals. By Joseph V. Woodworth. 8vo. 384 pages. 505 illustrations. [illegible]

A most useful book and one which should be in the hands of all engaged in the press working of metals, treating on the designing, constructing and use of tools, fixtures and devices, together with the manner in which they should be used in the power press for the cheap and rapid production of sheet metal articles.

ELECTRICITY.—The Standard Handbook for Electrical Engineers. Written and compiled by a Staff of Specialists. Second edition, corrected. 12mo. 1285 pages. 1200 illustrations. Bound in flexible morocco. $4.00

A new pocketbook consisting of twenty sections, each written by a specialist of engineering experience and containing the latest data and information regarding standard electrical practice.

ELECTRICITY.—Electrician's Handy Book. By T. O'Conor Sloane. 761 pages. 556 illustrations. Handsomely bound in red leather pocket book style. [illegible]

This work is intended for the practicing electrician who has to make things go. Although the principles of electricity and magnetism are treated, the greater part of the book is devoted to practical handling of machinery, details of construction and computations such as will be encountered in every-day practice.

GAS ENGINES.—Modern Gas Engines and Producer Gas Plants. By R. E. Mathot. 8vo. 314 pages. 152 illustrations. [illegible]

A practical treatise setting forth the principles of gas engines and producer design, the selection and installation of an engine, conditions of perfect operation, producer gas engines and their possibilities, the care of gas engines and producer gas plants, with a chapter on volatile hydrocarbon and oil engines.

GAS ENGINES.—Gas, Gasoline and Oil Engines. Including Producer Gas Plants. By Gardner D. Hiscox. 8vo. 442 pages. 351 illustrations. [illegible]

A complete book on the subject for gas engine owners, gas engineers, and intending purchasers of gas engines, treating fully on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude petroleum engines, with special information on producer and suction gases.

GAS ENGINES.—Gas Engine Construction. By H. V. A. Parsell and A. J. Weed. 8vo. 304 pages. 145 illustrations. [illegible]

A practical treatise describing the theory and principles of the action of gas engines of various types and the design and construction of a half horse-power gas engine, with illustrations of the work in actual progress, together with the dimensioned working drawings giving clearly the sizes of the various details.

HEATING.—Practical Steam and Hot Water Heating and Ventilation. By Alfred G. King. 8vo. 402 pages. 304 illustrations. [illegible]

An original and exhaustive treatise prepared for the use of all engaged in the business of steam, hot water heating and ventilation. The standard and latest book published. Describes all of the principal systems of steam, hot water, vacuum, vapor and vacuum vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation.

HYDRAULICS.—Hydraulic Engineering. By Gardner D. Hiscox. 8vo. 315 pages. 305 illustrations. [illegible]

A practical work treating on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits, the horse-power of falling water, turbine and impact water wheels, wave motors, centrifugal, reciprocating, and air-lift pumps, etc.

INDUCTION COILS.—The Design and Construction of Induction Coils. By A. Frederick Collins. 8vo. 295 pages. 160 illustrations. [illegible]

This work gives in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a ½-inch spark to a large one giving 12-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the descriptions are written in language easily comprehended.

LATHES.—Modern American Lathe Practice. By Oscar E. Perrigo. 8vo. 424 pages. 314 illustrations. [illegible]

A new book describing and illustrating the very latest practice in lathe and boring mill operations as well as the construction of and latest developments in the manufacture of these important classes of machine tools.

MAGIC.—Magic, Stage Illusions, and Scientific Diversions, Including Trick Photography. Compiled and edited by Albert A. Hopkins. 8vo. 568 pages. 420 illustrations. [illegible]

This very interesting volume is indispensable to the standard work on magic. It appeals to the professional and amateur alike. The tricks are all explained in detail, showing exactly how they are performed.

MECHANICAL MOVEMENTS.—Mechanical Movements, Powers, and Devices. By Gardner D. Hiscox. 8vo. 409 pages. 1,890 illustrations. [illegible]

This is a collection of different mechanical motions and appliances, accompanied by appropriate text, making it a book of great value to the inventor, the draftsman, and to all readers with mechanical tastes.

MECHANICAL APPLIANCES.—Mechanical Appliances, Mechanical Movements, and Novelties of Construction. By Gardner D. Hiscox. 8vo. 396 pages. 970 illustrations. [illegible]

This book, while complete in itself, is in fact a continuation of the author's "Mechanical Movements, Powers, and Devices." The author presents to the reader information regarding nearly all conceivable devices for producing motion or accomplishing mechanical results.

SPECIAL OFFER. These two volumes sell for $3 each, but when they are ordered at one time from us we send them prepaid to any address in the world on receipt of $5.

PATENTS.—Practical Pointers for Patentees. By F. A. Cresee. 12mo. 144 pages. [illegible]

Containing valuable information and advice on the sale of patents and elucidation of the best methods employed by the most successful inventors in handling their inventions. It gives exactly that information and advice about handling patents that should be possessed by every inventor who would achieve success.

PHYSICS.—Experimental Science. Elementary, Practical and Experimental Physics. By George M. Hopkins. In two volumes. 8vo. 1,105 pages. 915 illustrations. Cloth, $5.00. Half morocco. $7.50

This book treats on the various topics of physics in a popular way and describes with rare clearness and in detail the apparatus used, and explains the experiments in full, so that teachers, students, and others interested in physics may readily make the apparatus without great expense and perform the experiments without difficulty.

PLUMBING.—Modern Plumbing Illustrated. By R. M. Starbuck. 392 pages. 10¼ x 7¼. 55 full page engravings. [illegible]

A comprehensive and up-to-date work illustrating and describing the drainage and ventilation of dwellings, apartments and public buildings, etc. The very latest and most approved methods in all branches of sanitary installation are given.

PUNCHES.—Punches, Dies and Tools for Manufacturing in Presses. By Joseph V. Woodworth. 8vo. 483 pages. 702 illustrations. [illegible]

This work is a companion volume to the author's other work entitled "Dies, Their Construction and Use." It might well be termed an encyclopedia on die making, punch making, die sinking and sheet metal working.

RECEIPTS.—The Scientific American Cyclopedia of Receipts, Notes and Queries. Edited by Albert A. Hopkins. Containing 15,000 selected formulas. 8vo. 734 pages. Cloth, $5.00. Sheep, $6.00. Half morocco. [illegible]

Over 15,000 selected receipts are here collected, nearly every branch of the useful arts being represented. The alphabetical arrangement with abundant cross references makes it an easy work to consult. It has been used with equal success by chemists, technologists and those unfamiliar with the arts, and is a book which is useful in the laboratory, factory or home.

REFERENCE BOOK.—Scientific American Reference Book. Compiled by Albert A. Hopkins and A. Russell Bond. Containing 50,000 facts. 12mo. 516 pages. Illustrated. [illegible]

This book deals with matters of interest to everybody. It contains 50,000 facts, and is much more complete and more exhaustive than anything of the kind which has ever been attempted. It is indispensable to every family and business man. It is a book for every-day reference—more useful than an encyclopedia, because you will find what you want in an instant in a more condensed form.

STEAM ENGINES.—Modern Steam Engineering in Theory and Practice. By Gardner D. Hiscox. 8vo. 487 pages. 405 illustrations. [illegible]

This is a complete and practical work issued for stationary engineers and firemen dealing with the care and management of boilers, engines, pumps, superheated steam, refrigerating machinery, dynamos, motors, elevators, air compressors, and all other branches with which the modern engineer must be familiar.

TELEPHONE.—Telephone Construction, Installation, Wiring, Operation, and Maintenance. By W. H. Radcliffe and H. C. Cushing, Jr. 16mo. 171 pages. 125 illustrations. [illegible]

A practical book intended for electricians, wiremen, engineers, contractors, architects and others interested in the installation of telephone exchanges in accordance with standard practice. Intricate mathematics are avoided and all apparatus, circuits, and systems are thoroughly described. Selected wiring tables, which are very helpful, are also included.

TOOLS.—American Tool Making and Interchangeable Manufacturing. By Joseph V. Woodworth. 8vo. 535 pages. 601 illustrations. [illegible]

A complete practical treatise containing a valuable collection of drawings and descriptions of devices, the results of the author's own experience.

TOOLS.—Modern Machine Shop Tools. By W. H. Vandervoort. 8vo. 552 pages. 673 illustrations. [illegible]

A new and fully illustrated work describing in every detail the construction, operation, and manipulation of both hand and machine tools, being a work of practical instruction in all classes of machine shop practice.

WIRING.—Electric Wiring, Diagrams and Switchboards. By Newton Harrison. 12mo. 272 pages. 105 illustrations. [illegible]

This work is a thoroughly practical treatise on electric wiring in all its branches, beginning with the simple circuit and working up to the practical every-day problems, all being treated in a clear and intelligent manner. It is in every way a timely, well written, instructive work, [illegible] valuable as a guide for the wireman, engineer, contractor or electrician.

Any of the above books will be sent postpaid on receipt of price.

Our complete catalogue of scientific and technical books sent free on application.

MUNN & COMPANY, Inc., Publishers, 361 Broadway, New York

once more over the top sprocket drum and pulley where it meets the picture film traveling from the upper spool and the operation is repeated

The grave disadvantage of the revolving disk is that the screens therewith have to be as it were standardized that is to say, must be such that they are equally applicable to any picture that may be used in projection irrespective of the densities of the color filters used in photographing This often destroys or depreciates the true color effects and values On the other hand with the band it is possible to secure the same relative color screens that were used in taking the picture so that the latter is virtually projected through the same color filters as were employed for photographing

With the band moreover a new film can be far more easily fed into the machine In this apparatus the gateway is of special design The picture film has a short length of lead indicating successively red green blue in the order in which the exposures are made All that is necessary to do is to open the gateway superimpose the one color filter of the endless band upon its corresponding indication upon the lead and then all is ready for projection The apparatus has been demonstrated in London and Paris and the possibilities of the Friese Greene system owing to its simplicity and economy combined with truthfulness of color value and density have attracted considerable attention

◆

THE VISITING WARSHIPS—A COMPARISON

(Continued from page [illegible].)

point of bearing is most advantageous for her batteries and least advantageous for those of the enemy

Now from what we have said above it will be evident that when an all big gun ship meets one that carries a mixed armament of big guns and guns of medium caliber she will endeavor to place herself at sufficient distance from the enemy to be outside of the armor piercing range of its medium-caliber guns and within the armor piercing range of her own big guns She can only do this however by possessing a reasonable superiority of speed and the greater her excess of speed the more completely will she be master of the position

Applying these facts to the Connecticut Justice and Inflexible we can see at once how completely the all big gun high speed fighting ship of to-day outclasses the big and medium gun moderate speed battleship of the pre Dreadnought period The big gun ship is vitally vulnerable only by the penetration of her waterline or of the barbettes and turrets in which the 12 inch guns are mounted The greater part of the personnel of the pre- Dreadnought battleship on the other hand is stationed at the numerous guns of the secondary battery where they are protected by comparatively light armor and even at the fighting range of five miles they would be exposed to complete destruction by the high explosive 12 inch shells

Gun Power—Comparing the three ships on the basis of gun power we find that the Connecticut carries four 12 inch 45-caliber guns eight 8 inch 45 caliber guns and twelve 7 inch 50 caliber guns the Justice mounts four 12 inch 50-caliber guns and ten 7 6 inch 45 caliber pieces while the British Inflexible mounts eight 12 inch 45-caliber guns but no secondary armament Now at a fighting range of five miles the 12 inch gun of the Connecticut firing an 850 pound shell at 2 700 feet per second velocity can penetrate 8 inches of Krupp armor the 12-inch gun of the Justice firing a 731 pound shell with a muzzle velocity of 3,000 feet per second, can penetrate 7 inches of Krupp armor, and the 12 inch gun of the "Inflexible," firing an 850-pound shell at 2,900 feet per second, at the same range can penetrate 9 inches. Now, since the belt armor of the "Connecticut" varies from 11 inches amidships to 4 inches at the ends and that of the 'Justice varies from 11 inches to 5[illegible] inches at the ends it follows that the vitals of both these ships would be quite secure against the attack of the Inflexible at this range although it would be possible for her to penetrate both ships at each end of the waterline Since the 12 inch guns of both the Connecticut and the Justice are protected by from 10 to 1[illegible] inches of steel they should be practically safe against penetration On the other hand the Inflexible would not fare so well since her belt protection varies from 7 inches amidships to 4 inches at the ends and she would be theoretically penetrable by the guns of both her opponents at five miles range Her 12 inch guns however with their turret and barbette protection of 10 inches armor would be secure against penetration

It should be borne in mind however that these figures of penetration are worked out for impact *at right angles to the armor* At these distant ranges the projectiles would be falling at an angle of several degrees and therefore the resisting power of the armor on all three ships would be considerably higher than that mentioned above

The secondary armament both of the Connecticut and the Justice could riddle the unarmored but could not penetrate the armored portions of the Inflexible whereas the turrets and casements in which this secondary armament is mounted could be completely destroyed by the Inflexibles guns thus for the 8 inch of the Connecticut to penetrate the 7 inch belt of the Inflexible they would have to be within 5 400 yards of that ship, and the 7 inch battery would have to be within 4 000 yards while the 7 6 inch gun of the Justice would have to be within [illegible] 000 yards to effect penetration at normal impact On the other hand the 6 inch and [illegible] inch armor which protects the secondary battery of the Connecticut and the [illegible] inch and 4 inch armor on the turrets and bases of the secondary battery of the French ship would be at the mercy of the Inflexibles 12 inch guns

In this supposititious engagement to show the advantages of the Dreadnought type of battleship over the type with the mixed armament the Inflexible with an advantage of 6 to 8 knots of trial speed (it will be understood of course that an engagement would never be fought at these maximum speeds) would elect to place herself at the maximum effective range for her own guns which if the weather were clear would probably be not less than five miles Her higher speed would give her the same advantage which the weather gage or windward position gave to the old fighting frigates in the days of sail power and the smoothbore Her probable plan of attack would be to assume a position somewhat ahead of the leading ship and then concentrate the whole of her eight guns upon that vessel in the endeavor to cripple each ship in detail and it is an interesting question whether this concentration of fire on each ship in turn coupled with the vulnerability of the armored positions of the secondary batteries and the great exposure of the crews of those batteries would not go far to offset the lighter armor protection of the Inflexible By taking skillful advantage of her superior speed and if the gunnery on all three ships were equal it is conceivable that she might win the fight. Should she be getting the worst of it on the other hand her higher speed would leave her free to draw out of the conflict whenever her commander saw fit From what we have said however it is evident that ship for ship she would be more than a match for either vessel alone and in a duel she would probably close in to 6 000 or 7 000 yards and try to overwhelm the enemy quickly with her 12 inch guns.

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel

By JOSEPH V WOODWORTH

Size 6 x 9 inches 288 pages 201 illustrations Price $2 50 postpaid

This is a practical work treating on modern processes for the heating, annealing forging welding hardening and tempering of steel making it a book of great value to toolmakers and metal working mechanics in general Special directions are given for the successful hardening and tempering of steel tools of all descriptions including milling cutters taps thread dies reamers hollow mills, punches and dies and various metal working tools shear blades saws, fine cutlery and other implements of steel both large and small The uses to which the leading brands of steel may be adapted are discussed and their treatment for working under different conditions explained also special methods for the hardening and tempering of special brands A chapter on case hardening is also included

The American Steel Worker

By E R MARKHAM

Size 6 x 8 inches 367 pages 163 illustrations Price $2 50 postpaid

This is a standard work on selecting, annealing hardening and tempering all grades of steel by an acknowledged authority The author has had twenty five years practical experience in steel working during which time he has collected much of the material for this book Careful instructions are given for every detail of every tool Among the subjects treated are the selection of steel to meet various requirements how to tell steel when you see it reasons for different steels how to treat steel in the making of small tools taps reamers drills, milling cutters hardening and tempering dies pack hardening case hardening annealing heating apparatus, mixtures and baths, the best kind and why and in fact everything that a steel-worker would want to know is contained in this book

OUR SPECIAL OFFER: The price of these books is $2 50 each, but when the two volumes are ordered from us at one time we send them prepaid to any address in the world on receipt of $4.00.

NEW YORK, SATURDAY, OCTOBER 16th, 1909

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short* and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

EDUCATIONAL VALUE OF THE HUDSON-FULTON CELEBRATION

In view of the considerable cost, exceeding $1 000 000, of the Hudson-Fulton Celebration, the question has been raised as to whether any results have been realized or could possibly be realized that justify so great an outlay. If by results we are to understand any tangible commercial returns, it might be difficult to give a satisfactory answer, although it cannot be doubted that mine host of the inn and that innumerable army which caters to the physical well-being of a holiday crowd are more than satisfied.

To those of us who are in the habit of looking below the surface of things and who ever bear in mind the transcendent importance of the spiritual and moral over the merely material, it will be evident that the mere outlay upon the recent festival is of minor importance compared with the valuable gain to New York city, the Hudson River district and to the country at large, due to the close attention which that festival has directed to certain important events in the history of the United States and the correcting of certain serious historical errors concerning them.

Thus, in view of the far-reaching importance of his discovery, it was well worth the cost and trouble of the celebration to abolish once and for all the mythical "Hendrik" Hudson and have restored to the page of history the actual "Henry Hudson, Englishman," who sailed in a Dutch ship and under the Dutch flag after signing the recently discovered contract in which he is so named and thus designated. And it may be as well just here to explain that the total absence of the English flag from the elaborate scheme of decoration was perfectly proper, even in spite of the fact that it celebrated the feat of a British citizen. For the discovery of the river was made under the auspices of a Dutch company and by a ship which flew the blue, white and orange, just as that other great event commemorated by the celebration, the inauguration of steamship travel, was achieved by a vessel which flew the American flag. Technically considered, the exclusive use of the old Netherland colors and of our national emblem was correct, and had the scheme of decorations been thrown open to include the flags of all nations, it would certainly have lost much of that distinctive character which was one of its successful features. Now that the historical facts as to the real name and nationality of Hudson have been presented in such convincing form to the world at large, it is to be hoped that the mistaken spelling of the name will be carefully avoided in the interests of historical accuracy.

The other important truth brought out by the recent festival is the true relation of Verrazzano and Henry Hudson to the discovery of the Hudson River. The name of Hudson has been given to the river by practically universal consent, because he was the first navigator to make a complete exploration of the river throughout its navigable length, and to leave behind him a careful record of what he saw and did. He did not himself claim, nor as far as we know has anyone claimed, that he was the discoverer of New York Bay, an honor which we think should rightly belong to Verrazzano. The document which gives the account of Verrazzano's visit to New York Bay leaves the impression that his time was spent in the bay, and that the river he mentioned may have been the Narrows. Certain it is that the fact that the water at the mouth of the Hudson, if he ever entered that stream, was completely salt, and that the tidal currents were as strong in one direction as the other, must have given Verrazzano every reason to believe that he was at the mouth, not of a river, but of an arm of the sea. Verrazzano was a bold navigator, and his letter to Francis the First, describing his voyage, proves him to have been a close observer and capable of giving an entertaining description of what he saw. The genuineness of the letter, it is true, has been attacked, but the latest consensus of opinion among the historical authorities agrees to consider it as genuine.

For those reasons it is rather timely that the Italians of this city should have recently erected a monument to their fellow countryman, which will serve to connect his name with the famous harbor into which he sailed in 1524.

EVOLUTION NOT REVOLUTION

We have received so many requests for information about the widely discussed Melville-MacAlpine improvement in the marine steam turbine, and so many exaggerated statements have appeared in the public press as to the "revolutionary" character of this device, that we hasten to say the improvement is in no sense revolutionary, but is rather one important step in the evolution of the ideal marine turbine drive. Hitherto, the propeller has been placed on the same shaft as the rotor or rotating portion of the turbine. In the device which Westinghouse has built for Melville and MacAlpine, the propeller would be placed on a separate shaft from the turbine, and a reduction gear of five to one interposed between the shafts, thereby reducing the speed of the propeller to one-fifth that of the turbine.

Why is this improvement, supposing that in actual test at sea it proves to be as efficient as in the experimental tests, of such great importance? Why should not the turbine and propeller be upon the same shaft? Why should it be desirable to run one at a much higher speed than the other? The answer is that the steam turbine shows its best economy, consumes the least coal per horse-power, when it is run at high speed, whereas the propeller shows its best economy when it is run at a relatively low speed of revolution. This is true both of high-speed transatlantic steamships and slow-speed cargo boats. The propellers of the "Kaiser Wilhelm II," running at a speed of 85 to 90 revolutions per minute, show a propeller efficiency of from 60 to 65 per cent. The propellers of the "Lusitania," running on her trial trip at 180 revolutions per minute, showed a propeller efficiency of only 48 per cent. Had the "Lusitania" used larger propellers running at lower speed, the speed of the turbine would have been too low for efficiency, and results at the turbine end of the shaft would have been disastrous. On the other hand, had turbines been used on the "Lusitania" running at the high speed which gives a maximum turbine efficiency, the propeller efficiency would have been even less than the low figure of 48 per cent. The only way out of the dilemma was to use the present speed of 180 revolutions, which is too low for the best turbine results and too high for the best propeller results.

Now, what Melville and his coadjutors have done is to design a gear which is strong enough and runs with sufficient sweetness to transmit the great horse-power of a modern steam turbine without causing excessive loss by friction. When De Laval introduced the first practical steam turbine some fifteen years ago, he solved the problem by introducing a long helical gear, which reduced the speed from the several thousand revolutions per minute of the turbine to the working speed which was required on the power shaft. Apparently, what has been done in the new device is to master the difficult problem of providing a helical gear with a certain power of automatic self-adjustment, which will enable it to transmit several thousand horse-power without serious wear or heavy loss through friction.

Henceforth, if the gear shows good results in service at sea, it will be possible to secure the same horse-power with smaller turbines running at high speed, and to design the propeller with strict reference to the size and speed of the ship and the securing of a maximum effective thrust. Economy will thus be effected at both ends of the shaft, the engine room will become smaller, engine weights less, and the space and weight thus saved can be put into cargo and passenger space, or, in a warship, into heavier armament and better protection.

THE MOST POWERFUL NAVAL GUN.

In a certain respect big guns are like big battleships. At the time they are being built, it would seem that the limit of size and range had been reached, as indeed they have, for the time being. The progress toward improvement is so rapid, however, in these days, that hardly has one construction reached its supposed limit, before work is begun on another, bigger and better. A good illustration of this fact is had in the making of the largest and most powerful naval weapon in the world, namely, our new naval 14-inch breech-loading gun. This powerful weapon is nearing completion, and will be delivered to the Navy Department by the middle of October, for [illegible] at the Indian Head proving grounds.

The penetration of the new 50-caliber 12-inch guns to be installed on the new 26,000-ton battleships of the "Arkansas" class is given at 11 inches of Krupp steel at an extreme battle range of 9,000 yards. The thickness of the armor plate on the British battleship "Dreadnought" and her successors in the British navy is 11 inches at the maximum. This thickness of armor is being used on the new American warships now under construction. Up to the time of the construction of the 14-inch gun, the new American 12-inch gun, with its penetration of 11 inches of Krupp armor at 9,000 yards, was our most powerful gun. But that it has been greatly surpassed by the new piece is shown by the following figures.

The new 14-inch gun weighs nearly 64 tons, or 10 tons more than the 12-inch rifles built for the battleships "North Dakota" and "Delaware." Its total length is 53½ feet. The capacity of the powder chamber is 15,848 cubic inches, and it will require 365 pounds of smokeless powder to hurl the projectile of 1 400 pounds. After this huge shell is fired, it will travel a distance of 542 inches within the bore of the gun, and after leaving the muzzle it is good for a 25-mile flight. The range at which it would be fired in actual battle, however, would be about 9,000 yards, or five miles. The range of naval battles has trebled since the Spanish-American war, at which time 3 000 yards was the estimated range for a naval conflict, the guns being built accordingly. But now to outrange the "enemy" it has become necessary to build all American naval guns with a range of five miles.

The shell will leave the muzzle of the 14-inch gun at the rate of 2,600 feet per second, and its muzzle energy will be 65 606 foot tons. This is 12,000 more foot tons energy than that designed for the latest 12-inch weapon. So great is the penetrative power of this rifle that, when fired with a full charge, the projectile will penetrate 22.7 inches of the best Krupp steel armor plate at the muzzle, and at the range of 9 000 yards would pass right through a piece of armor 13 inches in thickness.

THE RECORD FLIGHTS OF ORVILLE AND WILBUR WRIGHT

Almost simultaneously in Germany and in America Messrs. Orville and Wilbur Wright made two new records of an entirely different kind on the second and fourth instant. The first record was made by Orville Wright at Potsdam, Germany, on October 2nd. He first took Crown Prince Frederick William on a flight of 10 minutes' duration at about 4:30 in the afternoon. During this flight the machine was driven to an altitude of about sixty feet. The Crown Prince was greatly pleased, and he urged Mr. Wright to go higher. Soon after alighting, Orville Wright started out again by himself, and for fifteen minutes he kept steadily mounting in circles until the areoplane was a tiny speck in the sky. After reaching the maximum height, which he estimated was about 500 meters (1 637 feet), he started in a swift descent. The machine came down at a terrific rate, and finally alighted safely about five minutes after it started the descent. Orville Wright said that the view he obtained was very similar to that he had when on board the Zeppelin airship, except that objects seemed smaller on account of his greater height. The height reached was not accurately measured, but from Wilbur Wright's statement to our editor that his aeroplane, if sent upward at its best speed, would probably ascend at the rate of three feet a second, it seems probable that Orville attained even a greater height than he believes himself to have reached.

The second record is that of Wilbur Wright, which was made about 10 A. M. on the morning of October 4th, when he started from Governor's Island and flew over the waters of New York Bay and above the North River to a point opposite Grant's Tomb. Circling around the British cruiser "Inflexible," he made the return trip close to the Jersey shore, at an elevation of only about seventy-five feet. On the upward journey he flew at a height of some two hundred feet, where he experienced considerable difficulty from the eddies and gusts of wind produced by the skyscrapers in the lower part of the city. A northeast wind of about twelve miles an hour velocity was blowing. On the return trip, the daring aviator kept on the other side of the river, and at a low elevation in order to avoid these gusts. The entire journey was made in 33 minutes and 33 seconds, the distance being about 19½ miles. This flight was not official, and Mr. Wright expected to repeat it in the afternoon. The weather conditions were ideal at 4 P. M., but just as he was about to start a cylinder blew off the motor, and effectively put the machine out of commission. As Mr. Curtiss had left the city the evening before after having made a short circular flight of a quarter of a mile, there was no more flying in connection with the Hudson-Fulton Celebration. Mr. Wright has already begun to teach two lieutenants to fly the government aeroplane.

ENGINEERING.

Steel manufacture by the electric furnace is making good headway At the present time there are in operation about 89 furnaces of the electric type, namely, 19 of the Hérault system, 14 of the Kjelling, 10 ot the Stassano, and the same number of the Roechling-Rodenhauser and Girol, the other twenty-seven furnaces being of eight other systems.

During the Hudson-Fulton Celebration week, the Interborough Rapid Transit Company of this city carried in the course of one day 2,300,060 persons without accidents, blocks, or other detriment to its service The traffic was about equally divided between the elevated roads and the subway Considering the crowded condition, this is a truly marvelous feat of city transportation

At last the Atlantic has been crossed by a steam ship at a speed of over 26 knots an hour the "Mauretania" on her last trip to the westward having covered the course from land to land in 4 days, 10 hours, and 51 minutes, at an average of 26 06 knots, reducing her last record trip to the westward by 44 minutes Although she did not reach her highest previous day's run, she maintained a steady high speed on every day throughout the course.

The monthly report of the Acting Chairman of the Panama Canal to the Secretary of War dated September 15th, states that during the month of August the total amount of excavation done on the Panama Canal was 2 755,178 cubic yards, the average rainfall being 9 27 inches. From now on there may be a diminution in the totals of excavation, due to the fact that portions of the canal have been finished and that as the excavation grows deeper, the number of shovels that can be employed will be reduced

The tests which are about to be made of the new army 14 inch gun at Sandy Hook will be followed with close interest, for upon the success of this gun will depend the character of the future armament of our sea-coast defenses. The new piece weighs about the same as the present 12 inch gun but fires a heavier projectile with lower velocity and a greater curve of trajectory Its great advantage is that it can fire 250 to 300 rounds without serious erosion as compared with the limit of 80 to 85 rounds for the 12-inch gun

The Bath Iron Works are to be congratulated on the remarkable speed made by the new torpedo-boat destroyer 'Reid" during her standardization trials on the Rockland mile course, when she reached a maximum speed for one mile of 34 55 knots. This is about a knot faster than the speed, which was itself a record for a torpedo-boat destroyer of the "Flusser' which made over 33½ knots The mean of the high-speed runs of the 'Reid" was 33 75 knots which is an eighth of a knot better than the average of the "Flusser" The shaft horse power was 15,000

The Japanese armored cruiser "Ibuki" which is equipped with the Curtis reversible turbine built by the Fore River Company has recently undergone successful steaming trials in Japan In the six-hour trial under full power, the steam chest pressure was 239 pounds, and the exhaust shell vacuum was 25 7 inches. At 250 5 revolutions per minute the brake horse-power was 27,142, and the water rate per brake horse-power was 15 03, corrected to contract conditions, it was 13 88 pounds. The "Ibuki" carries four 12-inch and eight 8-inch guns

The consulting engineer appointed by the city to pass on the plans and safety of the new Manhattan Suspension Bridge Mr Ralph Modjeski has found everything to be satisfactory The main tower foundations are good and sufficient, and although the foundation of the anchorages could have been improved by driving inclined piles, the fact that careful observation for the past sixty days failed to reveal any appreciable movement, leads him to consider that the foundations are safe and sufficient. The structure has been carefully designed and well built and will be amply strong to carry the heaviest traffic, as well as any reasonable addition in the weight of properly regulated traffic that it may have to carry for many years to come.

One of the most important works connected with the Panama Canal is the spillway in the middle of the Gatun Dam for regulating the height of the water in the lake. Usually it is preferred to locate the spillway in a position more or less remote from the dam, but in the present case the existence at the center of the site of the dam of a hill, which provided a rock surface at about sea level, proved the deciding factor, and led to the choice of the present site The spillway consists of a concrete dam, whose crest is to be built on the arc of a circle, with its face convex to the lake. The crest will be at 69 feet above sea level. Above this, and placed between thirteen concrete piers built at the crest of the dam, will be fourteen gates, whose tops, when they are closed, will be 87 feet above sea level. These gates will give absolute control of the lake level under all possible conditions.

ELECTRICITY

The Postmaster-General of the United Kingdom has secured for the government telegraphic system all the Marconi wireless telegraph stations in the British Isles.

A new combined electric lamp and shaving mirror has been produced, in which the reflector can be arranged to throw the light only upon the face below the eyes, no light falling upon the mirror or the eyes.

The British Antarctic expedition now in course of preparation will carry wireless telegraphic equipment sufficient to enable messages to be sent to New Zealand from the ship and from stations established at bases of supplies on land or ice

The Russia crown steel works at Slatons in the Ural district have secured the right to manufacture steel electrically by a process owned by a German company and using induction furnaces An electric plant will be immediately installed by the Siemens-Halske Company, and the product will be marketed directly

The electrified suburban system of the New South Wales State Tramways at Sydney, N S. W, showed a profit of $357 000 for the year ending June 30th 1908, after paying all working expenses and interest on capital as compared with a net loss of $15,500 a year for the steam lines owned by the State This encouraging result will probably cause extensive electrification in Victoria and other adjoining States.

The Commonwealth Edison Company of Chicago has been most successful with its plan of introducing electric flatirons Ten thousand 6 pound irons were distributed up to March last on loan for six months without charge At the end of that period the used irons were offered for sale at a reduced rate to the users most of whom were only too glad to retain the irons at so low a price while the demand for used irons returned has been greater than the company can supply

It is reported that a large wireless telegraph and telephone station is to be erected at the Omaha shops of the Union Pacific Railroad where Dr Frederick H Millener will conduct wireless telegraph and telephone experiments. Dr Millener hopes to develop wireless telephony to such an extent as to permit railroad officials to keep in touch with trains and thus govern their movements from sixty to one hundred miles from Omaha If the system is developed as he expects it will be possible for passengers on moving trains to carry on telephonic conversation within a radius of one hundred miles of Omaha

The rapid progress of aviation has caused attention to be drawn from a new direction to the dangers of atmospheric electricity In an article in the Elektrotechnische Zeitschrift Mr L Zehnder discusses the danger to balloons and aeroplanes of electrical disturbances and the methods of avoiding disastrous effects. He points out that the electrical conditions of the air are subject to great variations during thunder storms and that the atmospheric charges may change suddenly in sign In clear weather an ordinary balloon without metal parts is not exposed to any danger so long as it floats in the air but in the modern dirigibles much of the framework consists of conducting materials, which add to the danger Also a balloon may be charged with electricity and a spark produced when contact with the ground is made, setting fire to the gas

An ordinance was introduced at a meeting of the City Council of Chicago making it compulsory for all railroads operating within eight miles of the city hall to use electricity on their lines in place of steam There is every prospect that this ordinance will be passed as there appears to be considerable popular agitation in favor of it The ordinance requires that within a year after its passage and publication all railroads shall submit plans to the Commissioner of Public Works, and within six months after the plans and specifications have been approved they shall commence to electrify their roads If this ordinance is passed it will result in abating the smoke nuisance in Chicago to a large degree

The long lead in hydro-electric work maintained by the Pacific coast, which, with exceptional natural advantages, was early in the field is illustrated by the new power plant of the Great Western Power Company at Big Bend on the Feather River, Cal. the electrical equipment of which is described in the Electrical World The penstocks are the largest ever built for so great a head, the turbines themselves are of record size, 18,000 horse-power per unit, and are operated by what is certainly a record head of water for any turbines, 525 feet The transformers also are of record size, being three-phase units of 10 000 kilowatts capacity, with 100,000 volts on the high tension side Another big plant described in the same issue is that of the Grand Rapids-Muskegon Power Company which is remarkable for its high voltage generation, 110,000 volts being the highest yet attempted as well as for the simplicity of its arrangement.

SCIENCE.

Dr. F A. Cook has decided to submit to American scientific and geographic organizations duplicates of the proofs which are at the University of Copenhagen A simultaneous announcement is to be made in Denmark and this country as to whether he had furnished adequate proof that he had reached the North Pole

Ten grammes or about one-third of an ounce of radium chloride equivalent to one gramme of pure radium, is the total output for eighteen months of the Joachimsthal mines After the hospitals and scientific institutions have been supplied the remainder will be offered for sale at $75 000 a gramme or 15½ grains

Analysis of the natural gas coming from the Caucasus wells which is used for heating purposes, was made by M Meuschen as to the gas from the Bibi Eybat territory He finds the following composition in per cent Methane 54 80 hydrogen 13 58 saturated carbides 1 20 nitrogen, 20 42 oxygen 7 carbonic acid 3 Another sample gave only 0 80 hydrogen 60 0 methane and 25 nitrogen with the rest about the same

In a recent issue of the Astrophysical Journal Mr Walter S Adams of the Mount Wilson Observatory station summarizes the results of a study of the Mount Wilson photographs of sun spot spectra A discussion of the various elements whose lines are strengthened or weakened in the spot spectrum indicates that the changes observed may be best accounted for on the basis of a reduced temperature in spots A detailed study of the spectrum of iron furnishes especially strong evidence in this direction and the weakening of the enhanced lines in the spot spectrum is also most simply explained on the same basis The presence of the spectra of titanium oxide magnesium hydride and calcium hydride is sufficient to account for the greater part of the unknown fluting and band lines appearing in the spot spectrum The discovery of the existence of a magnetic field in sun spots by Mr Hale provides a ready and sufficient explanation for the widening of large numbers of lines in the spot spectrum for which there is no marked change of intensity

An apparatus for making enlarged tracings of sound-waves from a cylindrical graphophone record the magnification ranging from 150 to 2 500 times was described by F Proctor Hall before the British Association In the sound waves two elements are distinguished impulse and resonance which are illustrated by waves from the cornet, violin bugle etc Vocal waves are found in groups regularly repeated Each group contains a single impulse from the vocal cords together with one or more sets of resonance waves produced by vibrations of the air in the vocal tubes Pitch is determined by the number of impulses per second—i e by the number of wave groups—and is not affected by the character of the waves within the groups. The vowel quality of vocal sounds is not perceptibly affected by the number or form of the resonance waves but is dependent upon their periodicity The rate of the resonance waves may be calculated from the length of the air tubes upward from the vocal cords The calculation shows for example that the sounds *m* *n* *ng* all contain a resonance wave whose period is about 530 The mean rates found from measurements of the enlarged waves are for *m* 500 for *n* 535 for *ng* 580 The observed rate for the sound of *a* in the word great is 420 and for the sound of *a* in 'mat 770 waves per second

Mr Durand, United States Census Director has made an appeal to farmers all over the country to assist him in securing accurate agricultural returns at the coming census He trusts that farmers will keep or provide some sort of written record of their operations during the year 1909 Each person in charge of a farm will be asked to state the acreage and value of his farm—that is the acreage and value of the land kept and cultivated by him the area of land in his farm covered with woodland and finally that which is utilized for specified farm purposes the acreage quantity produced and value of each crop including grains, hay vegetables fruits cotton tobacco etc, raised on the farm in 1909, the number and value of all domestic animals poultry and swarms of bees on the farm on April 15th 1910 He will also be asked to state the number and kind of animals sold during 1909 and the receipts from such sales the number purchased and the amount paid therefor and also the number slaughtered for food and the value of such animals The census act provides that the information shall be used only for statistical purposes for which it is supplied No publication shall be made by the Census Office whereby the data furnished by any particular establishment can be identified nor shall the Director of the Census permit any one other than the sworn employees of the Census Office to examine the individual reports Furthermore the information reported on the agricultural schedule will not be used as a basis of taxation or be communicated to any assessor

The Employment of Liquid Air and Carbon Dioxide in the Treatment of Diseases of the Skin.

The lack of specific remedies for many diseases of the skin has caused a diligent search for new remedies more efficient or less disagreeable than those in common use An epoch in dermatology was marked by the introduction of Roentgen rays which exert a curative action in many cases of eczema attended with profuse exudation and intense itching in psoriasis and in many fungous diseases of the skin and hair Cathode rays have proven beneficial in numerous cases of lupus and quite recently malignant tumors of the skin have been cured by these rays

But in many cases treatment with rays failed to effect a definite cure and the experiments with other physical and chemical agencies were resumed An American physician tried liquid air and carbon dioxide and obtained more or less success in cases of tuberculous abscesses moles pimples and superficial cancer of the skin The method of treatment is as follows Cotton wool wound tightly on the end of a rod is dipped into the double-walled glass flask of liquid air and then pressed lightly on the affected part of the skin The skin freezes and becomes inflamed and in from 10 to [illegible] days the morbid growth sloughs off

But liquid air is expensive and it also acts too energetically An equally efficient but cheaper and more manageable agent is carbon dioxide which was first employed for this purpose by Pusey From the steel cylinder which contains liquefied carbon dioxide the vapor is allowed to escape into a glass tube Here it condenses into snow which is compressed by a piston into a hard mass This can be trimmed to the size and shape of the morbid growth to which it is to be applied and thus the freezing of the surrounding healthy skin can be avoided

The temperature of carbon dioxide snow is 110 deg F while that of liquid air is about − 290 deg F The snow is cold enough however to freeze the skin into a hard white mass in a few minutes Too long an application may cause necrosis or death of the underlying tissues The skin subsequently becomes slightly inflamed and a blister similar to that caused by a burn is produced In general freezing and burning produce similar effects on the skin In two or three weeks the part that has been frozen falls off as a scab revealing skin of quite normal appearance or marked by a slight scar The application of this remedy is not attended with great pain In the treatment of facial blemishes especial care must be taken not to freeze the skin too deeply The field of application of carbon dioxide snow is extensive Hitherto good results have been obtained chiefly in cases of lupus but small tumors callosities moles pimples etc have also been treated with success—Dr Bergrath in Die Umschau

◆

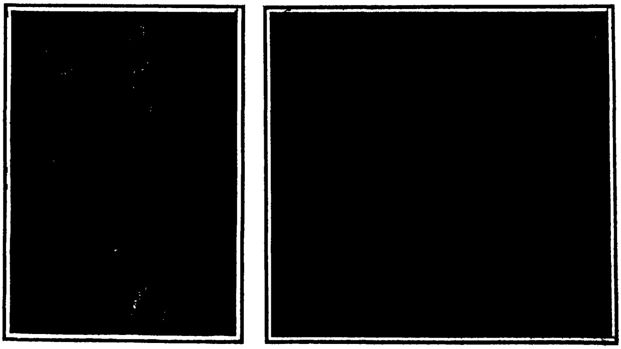
CYCLING TRICK IN A BERLIN VARIETY THEATER

The accompanying illustrations picture a trick performance which recently attracted much attention in Germany In the first photograph a cyclist is shown traveling outside a globular cage on a narrow wooden path He uses an ordinary bicycle wheel of 28 inches diameter and that of the globe is ten times as great viz 280 inches The circumference is consequently $280\pi = 8796$ or roughly 880 inches The globe is rotated by the friction of the cycle wheel on the top Every minute it makes 30 revolutions or 1 800 in one hour Any point of the equator travels a path equal to 880 times 1 800 in one hour or 1 584 000 inches As one mile is 63 360 inches it means that

$$\frac{1\,584\,000}{63\,360} = 25$$

miles are covered in one hour The cyclist must be very careful to keep in the center of the path By far the greatest difficulty lies in the fact that his weight constantly draws him down the slope in front as well as backward In other words he must not only keep his balance right and left but also forward and backward The latter feat he accomplishes by accelerating or retarding his bicycle

The other photograph shows two men inside the cage They rotate the globe through the frictional contact of their wheels with the globe



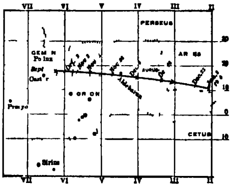
THESE TWO ILLUSTRATIONS REPRESENT A REMARKABLE BICYCLE TRICK WHICH ATTRACTED CONSIDERABLE ATTENTION IN GERMANY A GLOBULAR CAGE 280 INCHES IN DIAMETER IS FRICTIONALLY ROTATED AT HIGH SPEED BY AN ORDINARY BICYCLE.

◆

THE FIRST PHOTOGRAPH OF HALLEY'S COMET

The accompanying photographs of Halley's comet were printed from negatives made with the Yerkes two-foot reflector by Mr Oliver J Lee on the nights of September 24th and September 26th astronomical or civil on the early mornings of September 25th and 27th civil The photographs are here published by permission of the director of the Yerkes Observatory editor of the Astrophysical Journal in the October number of which magazine these pictures are appearing together with photographs taken on other dates On September 24th the exposure was from 13h 12m to 15h 42m central standard time on September 26th from 14h 47m to 1[illegible]h 47m central standard time The arrows point to the comet which is slightly elongated on the 24th due to the motion of the comet during a two and one-half hours exposure The picture is much enlarged and the stars shown are actually very faint none of them visible to the naked eye The brightest star in the field at the left of the comet on each day, is of magnitude 8 7 or about ten times fainter than the faintest star that can be seen with the naked eye without a telescope on a clear night. The faintest stars shown on the original plate are about twenty-five thousand times as faint as a sixth-magnitude star, the limit of naked-eye visibility The comet's motion in the sky at this time is comparatively slight and will be very much greater later The comet was retrograding or going westward at this time as seen from the earth (to whose motion this retrogression was wholly due) having ceased its eastward motion a few days before.

In this photograph of Halley's comet the arrows indicate the position of the comet At present the comet can be seen only through a powerful telescope



The path of Halley's comet from the date of its discovery to January 1910.

THE FIRST PHOTOGRAPH OF HALLEY'S COMET

The comet has been micrometrically observed on several nights with the forty inch Yerkes telescope by Profs. Burnham and Barnard On the 26th it was estimated by Prof Barnard to be of magnitude 14 or 14 5 with a diameter measured as 10 sec., but without definite boundary The presence of strong moonlight is likely to prevent the observation of the comet either visually or photographically for several nights after September 27th

A High School of Aerial Navigation in France.

It is due to the energetic efforts of Commander Rocher who has succeeded in enlisting the assistance of a committee the members of which are all well known in the scientific world that a special high school of aerial navigation has been organised in France on the following basis

1 All former students of the polytechnical schools, the schools of bridges and highways and mining engineering and of naval construction will be admitted as a matter of course Graduates of science (in general physics and mechanics) will be admitted upon passing examination in the drawing of machines Other places will be awarded upon open competition

2 The course of instruction comprises one scholastic year

3 The principal courses of instruction will be in all branches of aerial navigation aerostatics and aviation and about motors especially gas motors The annual lectures about the various topics are arranged in such a way that the students will be kept posted about all evolutions in aerial navigation and of the sciences relating to it

4 Independent of these courses of instruction the students will have to execute practical work relative to aerial navigation and to motors

5 To students who have completed all the courses as well as the technical work and have successfully passed the examinations the diploma of engineer of aerial navigation shall be awarded

6 Besides the regular students any person may attend one or several courses without however participating in the technical work and without being entitled to examinations or to the award of the diploma

7 The tuition fee for regular students is $200 The fees for other persons vary according to the number and the importance of the courses which they desire to attend

It seems only logical that France having been the first country to promote aerial navigation shall also be the first one to organize a higher course of instruction in same on a thorough and rational basis

◆

Another new hydro-electric plant is to be commenced shortly in Canada on the St Lawrence River near St Timothee Quebec The main features of the initial development are a canal intake and headgates about 3 200 feet below the present intake enlargement of the Beauharnois Canal from the intake to the station site a distance of 33 000 feet and turbines of 21 600 horse-power capacity The generators will consist of three 4 000-kilowatt turbine units two 350-kilowatt exciters, and there will be three 4 000-kilowatt transformers A transmission line 27 miles long to Montreal will be constructed, with transformer substations and distribution system there The present developments are expected to cost $4,000,000, the contract being let on the cost plus commission basis.

SAVING THE AMERICAN LOBSTER.

BY F HARVEY MIDDLETON

The little town of Wickford Rhode Island is the home of a most important and successful fish culture station. Here is situated a hatchery that has demonstrated the possibility of saving the lobster from the fate of absolute extermination The conservation of this favorite crustacean has been a perplexing problem for many years both in America and Europe Even Japan has recently taken a keen interest in the subject Until the last few years the most earnest efforts to propagate lobsters artificially have failed to offset the ravages of their enemies of the deep to say nothing of the onslaughts of man The steady decline of the lobster fishery emphasized the urgent need of more scientific methods

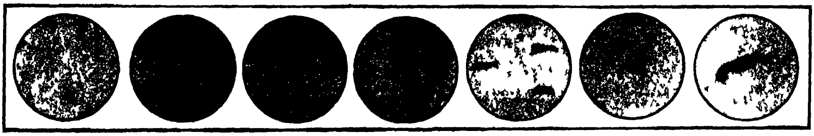
From the moment it breaks the egg membrane and emerges into the outer world the tiny lobsterling is at the mercy of every swimming thing—a choice delicacy that is devoured with equal impartiality by the plebian herring and the aristocratic bluefish For a time the minute translucent creature born with a voracious appetite ekes out a precarious existence on the microscopic organisms of the sea together with hundreds of its brothers and sisters born at the same time. As in our own world so it is in the lobster kingdom The more active get the most food and grow bigger and stronger than the less nimble And as soon as he realizes his superiority the larger lobster immediately starts devouring his smaller brethren Settling to the bottom of the water he will calmly seize the one nearest quite indifferent whether it is a near relative or merely a chance acquaintance The cannibalism of the baby lobster has always been the greatest impediment to the success of lobster culture

But confirmed cannibal though he is the lobster is nevertheless a timid nervous creature thriving only in the twilight and being most active after dark His natural home is in the cracks and crevices of the most rocky shores and he seldom ventures forth except in search of food which is dragged back to his retreat The stronger the light the more cautious he becomes and the daintiest morsel of chopped clam—his favorite dish—will not tempt him into the light of day If exposed to the sun he will wander nervously about until he finds a dark spot

A few years ago a little houseboat laboratory was started in the harbor of Wickford under the joint auspices of Brown University and the State of Rhode Island with the object of studying every phase of lobster life After numerous experiments Prof A D Mead who was in charge came to the conclusion that the secret of success in rearing the young lobsters was to keep the water in continuous motion thus preventing the little creatures from catching and swallowing one another This also kept the food in suspen

Cylinders in which individual lobsters are confined for observation

Drying a 12-foot lobster bag after it has been washed.



1 Lobsters in first stage of their development at which time they are one day old

2 Lobsters in second stage, having molted their skin once Four days old.

3. Lobsters in third stage of their development about eight days old

4 Lobsters in fourth stage having molted three times About two weeks old

5 Lobsters in the fifth and sixth stages of their development

6 Lobster in the seventh stage of his development

7 Lobster seven weeks old at which time he becomes recognizable

SAVING THE AMERICAN LOBSTER

sion so that the fry might obtain it. Simple as this solution of the problem was, no one had ever thought of it before

To prove the correctness of this theory, it was decided to experiment with the lobsters, which were at that time in small bags The water in the bags was stirred with an oar continuously for six days and nights The result was a brilliant success The evident efficiency of this crude method of stirring in maintaining the life of the young fry naturally suggested a mechanical contrivance for protecting the fry during the extremely critical period of their early life

Consequently a series of bags 12 feet square and 5 feet deep was sunk into the water and tied securely in place In each bag near the bottom was placed a two bladed rotating fan resembling that commonly in use over restaurant tables These fans or propellers were connected with vertical shafts which in turn were geared to a gasoline engine When the machinery was set in motion the rotation of the fans created a continuous current of water directed upward from the bottom of the bags, the force of the current being readily controlled by altering the angle of the blades This also prevented the accumulation of parasites on the young lobster's body

Scientists will tell you that from 30 000 new born larvæ which represent the average total mass of the brood produced by one pair of lobsters during their lifetime only one pair of mature lobsters are alive after a lapse of seven to nine years The lobster fishermen have been at their wits end to supply the ever increasing demand of hotel and restaurant for this popular sea food Now it bids fair to become so plentiful as to be within the reach of the humblest purse

Before the installation of the stirring device at Wickford it was the custom to turn out the young fry soon after hatching But the young lobster at birth is as helpless as a human baby with only feeble means of locomotion and no defensive weapons There are many stages in the life of a lobster at each of which he sheds his skin or shell and grows another It is not until the fourth stage that he assumes the familiar form of the lobster, and is able to defend himself to a certain extent

A successful effort was made to hatch the lobster eggs with the same stirring apparatus Female lobsters were obtained from Newport and the eggs were combed off in the ordinary manner and placed in the stirring bags When the propellers were set in motion these eggs were gently swirled about and hatched into very beautiful young lobsters

During the first three stages the lobsters swim near the surface in an aimless jerky way that reminds one of a wiggle tail The first stage lasts about three days the second about four or five days and the third usually about five or six days From nine to sixteen days are required for the larvæ to pass from the first to the fourth stage

A most marvelous change of form and an even more astonishing change of habits occurs at the third molt The emerging fourth-stage lobster has the general form of the adult The abdomen is no longer bent down at right angles to the body but as in the adult extends straight behind The downward stroke of abdomen which was the chief means of motion during larval life is now used as in the adult only for rapid retreat All five pairs of walking legs have lost their upper branches and the first pair which are now the la[illegible] characteristic 'nippers are extended straight in front of the head while the lobster is swimming These structural changes are accompanied by more radical changes in habits and instincts. The lobster no longer helpless upon the bottom burrows under shells or stones and picks out a home from which it sallies forth in search of prey In shedding its third skin it has cast off all its previous timidity, and with its strong crushing claw is ready to defend itself against all comers

A new style of swimming which lasts only a week or two is now adopted The tail being extended straight behind the body and the large claws extended in front of the head the lobster swims forward in a perfectly straight and definite course by the strokes of the swimmerets No trace of its former aimless activity remains for the lobster now actively seeks food avoids enemies and retreats from danger The active but careless and helpless infancy has been succeeded by enterprising independent youth The fourth stage lobster has passed the most critical period of its entire life and is vastly better fitted for the struggle for existence than at any earlier stage

In the first molts as in the succeeding ones the process is the same the old skin being split across the back between the thorax and the abdomen and the body working out through this opening leaving the cast-off skin otherwise intact The actual process of molting occupies only a few minutes but occasionally something goes wrong and the struggle is quite prolonged Often the lobster dies in the process and the period of molting is at best a very precarious one

Last year 294 896 lobsters of the fourth stage counted singly after being taken off of the hatching bags with a tea strainer, were liberated in various places along the shores of Narragansett Bay These thousands of lobsters have more value for the improvement of the local lobster stations than as many millions of larvæ of the first stage, with the setting free of which the experiment stations had previously to be satisfied But even after the lobsters have been reared to the fourth stage their future chances of life depend in some degree, on the time and place and manner of their liberation. Thus far it has seemed best to liberate them in the morning so that they may find hiding places and settle themselves before night falls and to scatter them over a considerable extent of territory, so that they may not gather in a conspicuous swarm

For years the United States Fish Commission has hatched at Woods Hole Gloucester, and at other stations many millions of eggs annually, and have set free the young as soon as possible after they were hatched But in this case the fry are distributed in deep water, and are thus in less danger from their natural enemies which like the mummychog and the shrimp abound in shallow water The apparatus used in hatching at Woods Hole is the McDonald jar into which the eggs are placed immediately after they are combed from the females In this they are kept swirling sometimes for weeks by a constant stream of salt water

The lobster ranges from Labrador to Delaware, and inhabits the waters from the very shore to a depth of more than one hundred fathoms It is thus confined to a strip of the Atlantic Ocean about 1 300 miles long and at some points as the coast of Maine from 30 to upward of 50 miles wide The number of eggs or seed carried by the female on the under surface of her tail varies from 10 000 to 20 000

At Wickford the young lobsters are raised from the egg to maturity In order to determine not only their habits and requirements at various stages and in various seasons but to ascertain as nearly as possible the normal rate of growth When the fourth stage is reached a number of lobsters are put into cars provided with sand, gravel and seaweed to stimulate as closely as possible the natural environment The sides of the cars are made of galvanized iron screening which allows a free circulation of water

During the summer the cars are suspended from the house boat or from floats so that the water in them is about eighteen inches deep In the fall they are provided with tight fitting covers and sunk in the channel in from eight to ten feet of water, and left undisturbed until spring The lobsters are frequently fed during the summer on chopped clams fish and several other varieties of food but in the winter no food is given them although they may obtain some food from the water or from the animal organisms which grow in the car The cars seem to furnish a natural environment for not only are the lobsters in a healthy condition but seaweed oysters clams, mussels shrimp tunicates barnacles various specimens of marine worms and other animals grow inside of the cars as rapidly and normally as in other places

An interesting part of the work at Wickford is the liberating of a number of lobsters with copper tags attached to them Last summer 210 were set free with tags bearing a number and the words 'Return to the Rhode Island Fish Commission" Thirty-six of the tags were returned by lobstermen with the date and place of capture and valuable information on the movements of the lobsters was thus obtained Although the greater number returned had not wandored far some had made their way southward for several miles The lobster bearing the tag 75" shown in the photograph which was caught one mile southwest of Beaver Tail holds the record up to date for fast traveling having covered a distance of ten statute miles in less than eight days

Correspondence.

THE FLOORS OF PANAMA LOCKS.

To the Editor of the SCIENTIFIC AMERICAN:

I notice in your last week's issue an interesting description of a plan for anchoring down floors of locks in the Panama Canal, to prevent lifting and injury by upward pressure of seepage water

As an unbiased bystander, "watching the game," I venture to suggest that any possible pressure of the kind feared could be easily relieved by providing small openings at intervals in the floors of locks, with steel tubes extending vertically from upper to lower surfaces, with valves which could be opened to allow seepage water to flow into locks freely during inspection.

Such safety valves could be inserted with very much less expense than anchorages proposed. Would some of your readers interested in hydrostatics kindly point out any practical objections there might be to such a procedure? R. ARMSTRONG.

Rock Park, Ramona, Cal.

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN

Will Mr Solon De Leon kindly give us his authority for his "consanguine groups"? The more the habits and customs of primitive peoples are studied, the more it becomes apparent, I believe, that they have, and had strict rules preventive of all close interbreeding I am not in a position to name authorities, but have just been reading John Rhys's "Studies in the Arthurian Legend," in which, referring to such matters, he says 'Celtic mythology fails to carry us back to a state of society where it could have been possible" (See page 227) Mr Eckles's isolated communities were bad enough, but now we have Mr De Leon's family groups, all the daughters of which were wives of all the sons, yet science is emphatic in teaching that all inbreeding whether of plants, animals, or man is fatal, and leads to the degeneration and extinction of the race And Nature confirms the same. These gentlemen greatly exaggerate the conditions, I think or surely we should all have vanished off the scene centuries ago! If "consanguine groups" ever existed it must have been in the very infancy of the race and certainly could not be placed within the last 25 000 or 30,000 years.

Should it be true that it is next to impossible to find any two Englishmen who have not an innumerable number of ancestors in common then it can only be a question of time when the same truth would apply to all human beings We are told that everything is possible in this wonderful world except logical contradictions, are not these theories a fair example of such? Isolated and consanguine groups would tend to keep the general population separate and so cut both ways. In any case the problem as given in my last letter in your issue of September 11th remains unaffected Such a case of intermarrying as F W A specifies must surely be very rare indeed!

Doubtless the intermarrying of relatives explains much of the puzzle but it will not bear all the weight some of your correspondents are willing to risk upon it.

Los Angeles Cal A K. VENNING

The Current Supplement.

Just now the popular conception of Fulton is that of a man who invented steam navigation. A critical consideration of what he really did is presented in the current SUPPLEMENT No 1763 The very high power which is now demanded of naval ordnance, especially the main armament of battleships, has led generally to a consideration of the utmost importance—the life of the guns. This question will be found admirably discussed in a thorough article. Well-equipped experimental laboratories are indispensably necessary for the progress of aviation One of these is the Aerodynamic Institute of Kutchino, which is well illustrated and well described Steam turbines may be governed in several ways, which are considered in a carefully prepared article. The admirable résumé of importance in the internal-combustion engine begun in a recent number by Mr H E. Wimperis is continued The old dusty road that winds from the landing of the village of Capri to the mountain top behind the village will no longer be used by the tourist A cable railway now takes its place This railway is described and illustrated E. Sherwald writes on some decorative designs derived from the polarization figures of quickly-cooled glass. Prof L. Jaloustre contributes a simply worded article on catalysis. G Espitallier discusses building methods in the earthquake regions. The makers of arc lamps have several times devised more or less ingenious lamps, in which the clockwork or motor by which the carbons are moved as they are consumed is suppressed Most recent attempts of this kind are to be found in the Beck arc lamp, which is described in the SUPPLEMENT Oliver Light contributes a suggestive article on the making of automobile repairs.

STRANGE SCIENTIFIC ANOMALIES AT THE NORTH POLE.

BY JAMES ARTHUR.

In the illustration, Fig. 1, *N S* is the earth's axis, on which it rotates, *with reference to the sun*, in 24 hours of mean or clock time. This axis is purely imaginary, yet the fixity of its position is one of the fundamental facts in astronomy The same remark applies to the earth's rotation on this imaginary axis. When we remember that the earth is nearly as heavy as a ball of iron, and that the surface velocity at the equator is about 17 miles per minute, we can form some conception of this uniformity Mathematicians lead us to conclude that this rotation and its axis, or center line of motion, are not eternal and that they will change, but for the historic period we may consider them uniform and permanent. Finally, they are the nearest to absolute uniformity and fixity that we know of. A minute slowing of the rotation would not disturb anything, beyond keeping the astronomers busy correcting their tables, including those of our erratic neighbor, the *moon*

Did you ever think what would happen if the axis of rotation changed a little? The polar diameter of the earth is about 26 miles shorter than the equatorial diameter, therefore each pole is "flattened" 13 miles, so the section of the earth, if split through the plane of a meridian, would be elliptical Remember, this is the *sea level* form of the earth Now let us suppose the axis to be changed so as to *reduce* the latitude of New York by bringing the new equator nearer to the city The city would then be covered by the waters of the Atlantic and the land near the new poles would be left high and dry That is, the ocean level would *rise* on New York and *fall* at the new polar region On this assumption—that the axis could be changed on the meridian plane of New York—two very interesting and impressive questions arise

1st. What diminution of latitude would raise the waters of New York Bay one thousand feet, and thus cover the city with Atlantic water?

2nd What increase of latitude would lower the waters of the bay forty feet and leave all New York docks simply mud holes?

Clearly it is perilous to disturb the earth's axis.

Refer to Fig 1, where the sun *A* is shown *on the line* at the spring equinox An observer on the equator at *E* would see the sun on the celestial equator just where he is, that is half his face on each side of the celestial equator An observer at the North Pole *N* would see the sun the breadth of his face higher at *B* than his real position *A* An observer at *S* would see him at *C* This is caused by the refraction of the sun's rays in passing through the atmosphere, and it is a remarkable fact that the average amount of this refraction at the horizon is just about the breadth of the sun's face, so that the three suns seen by the observers *N E S* would touch one another as shown

Now let us assume level land within the Arctic circle and that we have built an astronomical observatory on the pole To make things balance, let the observatory be built in the form of an Irish 'round tower" How would we know the location of the pole so that we could build an observatory on it? "Oh" you say, 'that would be easy Just build it plumb under the pole star" Not at all. If we did that, we would be about 85 miles *from* the pole The reason of this is that the so-called "pole star" is only the nearest bright star to the "polar point." This popular pole star makes a daily circle around the "polar point" about 4½ times as broad as the sun's face and we must make the sharp cone of our round tower point to the center of this circle Then we would have a "pole" worth speaking about.

Sitting in the top of this tower what would you see? The sun sweeping around the horizon once in 24 hours, but a little higher each day in a grand spiral course in the celestial sphere, as compared with the horizon In a little over three months he would be above the horizon 23½ degrees, and this would be the middle of the "great day"—and the longest day at New York.

We are now in a position to make some wonderful and unusual experiments and observations. One of the delicate experiments would be to determine the length of a pendulum beating seconds at the pole This would enable the mathematicians to correct their figures as to the form and density of the earth, two matters of great astronomical importance In this observatory we would determine any meridian such as Greenwich and get its local time as easily as in any observatory south. Now stand with your back to the pole (round tower) facing south on the "first meridian" and walk down this meridian a little over three and one-half miles till you come to a circle of latitude 24 miles in circumference *G* Fig. 2. Now face west with your right hand to the pole, and stand there till your shadow points straight to the pole. This would be noon at Greenwich Start walking due west on the circle *G M* at the rate of one mile per hour. As you walk what changes would you see? None whatever but your shadow would steadily point to the North Pole (round tower) and the sun would appear to stand still in the sky. You could see only the motion of your feet over the ground. What were you doing during this 24-hour walk? With respect to the sun you were not moving, but simply *treading the ground* with your feet. On this 24-mile circle of latitude you were walking one mile an hour *west* but as the earth rotates one mile an hour *east* on this circle you were just neutralizing its motion and making no headway with reference to the sun Let us now go out to a circle of latitude of 48 miles circumference *O P*, and on each of the 24 meridians here draw a circle two miles diameter These circles would just touch one another, as shown on Fig. 2 Set up a flagstaff in the center of each of these circles. Divide each circle into 24 hours, marking 12 on the meridian, on the side of each circle toward the pole Only the Greenwich and New York dials are divided in this illustration You have now 24 sundials, each *one giving the local time* of its meridian, and it would be *noon* on each meridian when the shadow of the staff pointed straight to the round tower on the pole Now consider the shadow of our round tower observatory at Greenwich noon

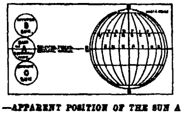

Fig 1 —APPARENT POSITION OF THE SUN AT THE EQUATOR AND AT THE POLES.

when the staff shadow points to the pole on the meridian *of zero, then the shadow of the sharp tip of the* tower would fall on meridian 180 degrees and indicate midnight, or 24 o'clock on that meridian and so for all other meridians We would thus have *noon* and *midnight* on each of the 24 meridians every day These 24 dials would read consecutively one hour apart This 180th meridian is the theoretical 'date line, or beginning and ending of a date Since a day is always beginning and ending at the 180th meridian you could walk from to-day into tomorrow or from to day into yesterday as often as you pleased But if you sat in the center of the observatory on the pole you would have all times in the 24 hours and no particular time No local time—no north east or west You could move only south at the first move Your parallel of latitude would be a point Your meridian would be all the meridians—and none of them' Any wind passing over the pole would blow *from* the south and also *toward* the south at the same time. If you tried to go farther north you would be going south

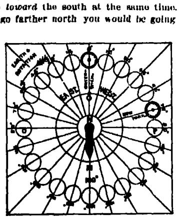

Fig 2.—DIAGRAM ILLUSTRATING ANOMALIES OF TIME AT THE POLE.

These suppositions have been made for about the middle of the great polar day, but this day is worthy of some attention. Probably you suppose that it means simply six months day and six months night You are wrong As shown above, in connection with refraction the sun at the spring equinox is clear above the horizon and the same at the autumnal equinox, as shown in Fig 1 If you will add to this refraction the slight dip of the horizon, as seen from the tower observatory and also a few days of twilight morning and evening of the 'great day, you will have several days more than half a year But this is *not all for* the sun is almost four days more than half a year *above* the celestial equator that is *four days* longer than half a year between the spring and autumnal equinoxes. All *these* lengthen the "great day' so that it would be a good practical working day of about seven months. Remembering our assumption of *level land* and clear weather in the polar region the apparent motion of the sun would be wonderful He would appear simply to rise straight up and then down but his daily course *around* could be observed only by shadows, or from the observatory so that in the open for a short period, he would appear absolutely fixed in the celestial sphere.

How would the moon behave? During the great day she would be only above the horizon along with the sun, and show *only third quarter—dark—first quarter*, so would be invisible in the glare of the sun Let us now assume about the middle of the great night The moon would rise in the first quarter, and as she slowly climbed up her face would come nearer to being *full* till in a little less than seven and a half days she would stand up full at her culmination of 23½ degrees above the horizon She would sink at the same rate, gradually coming to the third quarter as she set. To use popular language the moon would rise half face bright—creep up to full face—and then sink to half face again as she set remaining up steadily for nearly fifteen days During the time she was visible she would sweep the heavens—compared with the sun, not once in 24 hours—but once in 24 hours and 50 minutes This is caused by her monthly motion which is *against* her apparent motion in the sky We thus see that the moon rises and sets each lunar month just as the sun rises and sets each equinoctial year City people do not notice this very often but the old farmer needs the moon and puts it in round numbers the *moon* rises three-quarters of an hour later every night" All this is the average an observer would see but by using instruments he would find many variations in the moon's motions

Let us suppose that the moon has set thus leaving us in the black polar night till the next moon about a fortnight hence What motions would you look for in the stars? None whatever, the whole celestial dome would appear to stand still day after day Stars near the horizon would stay there and those overhead would show no motion But if you went into the observatory and turned a telescope on any star you would find it moving horizontally Stars at the horizon would move the fastest and as you pointed your telescope higher and higher they would move slower and slower till you reached the pole star ' which as noticed above, would move in a little circle of less than 2½ degrees the center being the polar point 'dead plumb' under which stands our observatory This slowness and fastness *of the* various stars is caused by the fact that they all make a horizontal circle in a sidereal day of approximately 23 hours 56 minutes If you wish more information about this sidereal day —the 24-hour sun day and the moon day of 24 hours and 50 minutes—you must go to your cyclopedia or still better call at the Naval Observatory in Washington, D C as space cannot be taken here

An Opinion of the Scientific American Supplement

In The Publisher and Retailer for September 1909 appears a communication which displays not a little knowledge of the SCIENTIFIC AMERICAN SUPPLEMENT not only from an editorial standpoint but from the publisher's standpoint The writer states

A remarkable periodical is the SCIENTIFIC AMERICAN SUPPLEMENT a sterling weekly established in 1876 The original idea was that it should run out that year and concern itself with the Centennial Exposition which made *Philadelphia famous But the* SUPPLEMENT found itself firmly anchored at the time the owners *had planned to kill it and it has been continued* weekly ever since The remarkable things about it are several—perhaps the most so is that it prints no advertisements though it is a meaty sixteen pager of the size of Collier's For revenue its publishers look only to the circulation end of the game It is so far as your uncle knows the only *bona fide* advertisementless periodical in existence A file of the SUPPLEMENT is in a scientific way the greatest of encyclopedias nothing finding place in its pages unless of practically permanent interest and value Even remarkabler probably is the fact that all numbers of the SCIENTIFIC AMERICAN SUPPLEMENT are kept constantly in print -ten cents will purchase a copy ten twenty or thirty or more years old as readily as a current issue The sale of back numbers warrants the publishers in keeping in print the seventeen hundred issued since January 1876 To make sale for the back numbers a catalogue is issued from time to time and in this is revealed the contents of all the issues which have gone before Remarkablest perhaps is the fact that while the SCIENTIFIC AMERICAN is on sale to the trade and for which there is no back number sale the SUPPLEMENT is not whereas one would think it is the one which should be made returnable as returned copies would not be dead stock as must be the case with the other publication'

The Publisher and Retailer circulates largely among newsstand dealers and the SUPPLEMENT is not designed primarily for newsstand circulation Hence this opinion of its virtues addressed to a class of dealers who are not likely to be interested in its editorial merits is all the more acceptable

* * *

From a report of comparative tests made by an American trunk line on the new ferro-titanium steel rails and those of the Bessemer type it is noted that the wear on the former showed 1 45 pounds per yard as against 4 18 pounds per yard on the latter which is nearly 300 per cent in favor of the new alloy steel

PLAYING A 'CELLO BY COMPRESSED AIR.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

At a recent concert in London one of the programme features was a violoncello solo, rendered in conjunction with the "auxetophone" the invention of the Hon C A Parsons of turbine fame. Through the courtesy of the inventor we are enabled to describe and illustrate this novel attachment to musical instruments whereby the tone of the latter, to which it is attached, is appreciably increased by means of a current of compressed air

The auxetophone may be best described as a comb or multiple-reed valve of aluminium which comb is hinged in such a manner that each tooth of the comb can vibrate at a variable distance from a corresponding slot in a little box to which compressed air is supplied at about five pounds pressure The farther away the teeth are from the slots the greater is the flow of air and *vice versa*. The flow of air is controlled by a valve and when caused to vibrate the air transmits corresponding sound waves into the trumpet.

When the auxetophone is applied to the 'cello or any other stringed instrument, the valve is connected by a rod of aluminium with the bridge of the instrument Thus the valve is caused to vibrate in accord with the characteristic tone of the instrument. The sound issuing from the trumpet though in many respects identical with that of the instrument itself is at the same time richer in character and greater in volume

In the accompanying illustrations the disposition and details of the apparatus are clearly shown A special bar is carried across the sounding box of the instrument to support the multiple reed valve and its box The current of compressed air enters the box at its lower end The aluminium connecting rod between the valve and the bridge of the instrument is clearly shown

The air is compressed in a small portable cylinder The current first passes through a pressure gage at the player's foot the dial of which can be instantly and easily read and followed From the pressure gage it passes to a small air filter which removes all suspended impurities. Then it passes to the lower end of the valve box mounted on the instrument. Between the pressure gage and the filter is a small pedal, by means of which the player can modulate the flow of the compressed air by means of his foot

The horn is mounted on a stand beside the instrument and a flexible pipe coupling connects the valve box of the instrument with the horn The valve mechanism support is so made that it can be attached to or detached from the instrument in a few moments

At the concert previously mentioned, the possibilities of the invention were very strikingly evidenced The tone of the instrument was appreciably fuller richer and stronger when the auxetophone was attached the harmonics were clearer and the high pitched notes were more clearly defined than is possible without the attachment. In the fortissimo passages the tones had a solid well-rounded ring of great volume while in pianissimo the expression of the artist was well produced with a softness accompanied by distinct clearness of the tones.

Timber is scarce at Tucson Ariz and fence posts are expensive Recently states the Industrial World the manager of the Tucson Rapid Transit Company found it necessary to string some wire fencing and in lieu of fence posts he cut up a lot of old boiler tubes into suitable lengths and made holes in them to attach the wire fencing He made some convenient gates by sliding 4 inch tubes inside of 4½ inch tubes the collapsible tubes serving the purpose of cross bars. Recently, in sinking a well for power-station circulating water, he utilized the shells of two water-tube boilers, sinking them one above the other to a depth of 36 feet.

The Budde Hydrogen Peroxide Process for Sterilizing Milk.

The problems confronting a public pure milk supply are only too well known. The greatest difficulties arise from the fact that trade milk is drawn from so many quarters and such a varied assortment of sources and then promiscuously mixed, that even if the supply from one set of cows should be pure, it is immediately contaminated by its admixture with the product from other doubtful cattle Sterile milk in the generally accepted sense of the word is practically impossible to obtain Numerous methods have been evolved for treating milk so as to render it perfectly innocuous. Scalding or boiling are the most commonly favored means for destroying germs but heat destroys the character of the article and in artificially fed children it is invariably productive of rickets and other serious infantile maladies In pasteurizing milk no two dairymen adopt the same degree of temperature

Within recent years the tendency has been toward the use of a powerful antiseptic such as hydrogen peroxide. Although highly successful in its results, the use of antiseptics requires care, since otherwise the requisite effect is not achieved or the taste of the milk is quite changed A Danish chemical engineer C Budde, D.Sc, of Copenhagen, has for some time been prosecuting his investigation along these lines and after prolonged experiment has succeeded in evolving a process which has received the indorsement of such eminent bacteriologists as Prof Von Behring, Dr Rideal, Prof Tanner Hewlett, and other well known luminaries at the leading institutions of Europe. So effective is it in its application, that buddeised milk, as it is generically termed, is becoming extensively consumed not only in Denmark but other European countries and Great Britain

Although it appears somewhat elaborate in comparison with the popular dairy methods, the process is so inexpensive as to enable the purified milk to be sold at the customary price. The milk upon collection from the various farms is brought to a central depot, where it is raised to a temperature of 122 deg In this heated condition it passes through a centrifugal cleaning machine similar in design to a separator, but having only one outlet, the cream not being separated from the milk. This operation not only removes all particles of dirt suspended in the milk more effectively than ordinary filtering, but also serves to arrest any bacteria that may be adhering to the foreign articles and to the minute motes of the tissues of the cow which are always present in milk. It may be mentioned in passing that such cleaning the inventor maintains to be necessary in any milk treatment, since experiments have proved that the bacilli adhering to these different particles are the most resistant. Striking illustration of the extent to which dirt is present in milk is afforded by the amount of residue that is found in the bowl of the centrifugal cleaner after the raw milk has passed through

From the cleanser the milk passes into a water-jacketed glazed earthenware vat, in which it receives the predetermined quantity of hydrogen peroxide (H_2O_2) The temperature of the water jacket can be raised to the requisite degree and maintained thereat merely by the admission of steam The vat is fitted with a mechanical stirrer, which is actuated from time to time to create and maintain a homogeneous mixture. The peroxide is perfectly harmless when taken in small quantities. The amount used by Dr Budde is very minute The chemical is added to the fluid when heated to the temperature of 122 deg. F

The effect produced upon the milk by the hydrogen peroxide is that the enzyme catalase, first isolated by Loewe at Washington in 1901, attacks the hydrogen peroxide, and immediately decomposes it into water and oxygen. The result is that the one volume of oxygen thus released—hydrogen peroxide consists of two equal parts of hydrogen and oxygen—immediately seizes upon another atom of oxygen Consequently, for a very short moment the oxygen is in the form of unic atoms, and exercises a far greater inclination than ordinary oxygen to combine with the oxidizable substances present, which fact explains the well known powerful oxidizing qualities of the hydrogen peroxide. It is imperative that the H_2O_2 be chemically pure

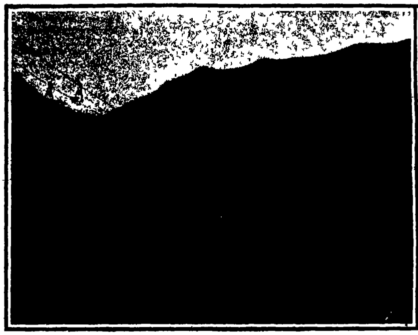
The product has been subjected to prolonged searching tests by eminent Swedish, Danish Austrian and German scientists and bacteriologists, who have pronounced an eminently favorable verdict thereon Possibly the most striking of these investigations were those carried out by Dr Th Begtrup Hansen at the Silkeborg Tuberculosis Sanatorium in Denmark in comparison with raw and pasteurized milk. The results of those observations were completely satisfactory It was found that the patients partook of the buddeised milk readily and found it agree well with them, it was well absorbed and possessed good nutritive value, and in certain cases of gastric and intestinal disease agreed better with the patients than pasteurised milk, while no ill effects arose from the method of sterilization. Its greatest advantage, however, was its sterility, while the fact that it insured the destruction of tubercle bacilli in mixed milk from several cows, such as ordinarily exists in trade milk, i e., that generally provided for the public, was especially commented upon.

◆

The wireless telegraph stations along the British coast established by the Marconi Company and the Lloyds have been taken over by the British Post Office, and hereafter will be operated by the government. The long-distance stations, however, at Poldhu, Cornwall, and Clifton are not included in the transaction and still belong to the Marconi Company This act of the British government will no doubt mark an important step in the commercial use of wireless telegraphy, because the Marconi Company has heretofore refused to communicate with vessels not equipped with the Marconi system of wireless telegraphy The British government will of course make no such distinction.

MOVING A MOUNTAIN IN UTAH.

One is accustomed to think of mining operations as being conducted deep in the bowels of the earth, and of miners working in cramped positions and an unwholesome atmosphere of powder-smoke and grime. In Utah, however, mining operations are conducted for the recovery of metal on a truly enormous scale, out in God's good air and sunlight, in the course of which a mountain is being leveled instead of caverns being hollowed out within the earth's crust.



Aerial cable tramway sending down to the railway ores from the Utah Apex mine.

One of the "benches" above the tramway shown in frontispiece of this issue.

Nor are the unusual, even sensational methods of mining adopted the only interesting features in the history of the Boston Consolidated and adjacent mines at Bingham Cañon, Utah. In all the history of mining, always fascinating by reason of its surprises, there is no story more romantic than that of the transformation of the Highland Boy, on the verge of failure as a gold mine, into one of the largest copper producers of the world.

The iron gossan outcrop in Bingham Cañon had long been a local landmark, and was known to contain gold to the value of $4 to $8 a ton, but in a very refractory state. In 1895 the Highland Boy mine, upon which considerable development work had been done, was offered for sale as a gold mine for $300,000 and refused after examination by a Montana syndicate. Ten years later the Utah Consolidated Copper Company, with that mine as its principal asset, made a profit of $2,750,000 in a year, and is still making an increasing output.

Copper is the determining factor that has made all the difference.

In 1896 Mr. Newhouse secured sufficient capital to erect a cyanide plant, and the mine was a fairly profitable gold producer for a time, but profits dwindled and ceased, surplus capital evaporated and total failure seemed imminent, when toward the end of 1897, rock that was going over the dump as waste was found to contain 8 per cent of copper. The lowest development adit had penetrated a large body of iron pyrites containing enough chalcopyrite to bring it up to the above value.

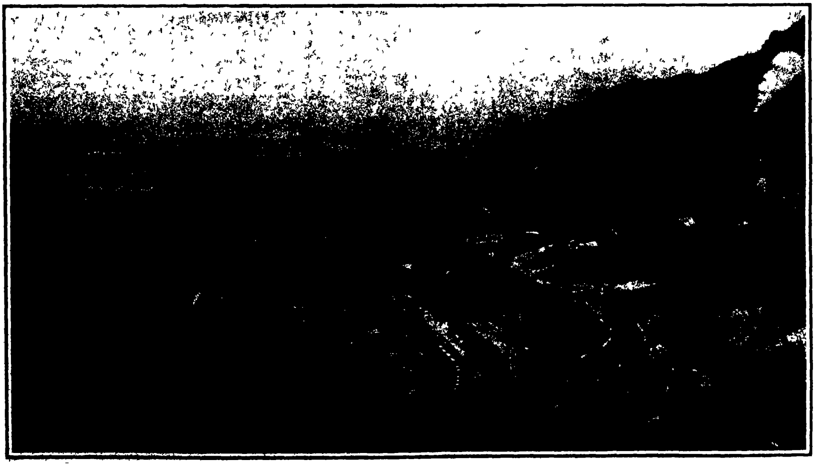
Prospecting in the same neighborhood by Col. E. A. Wall's associates disclosed a great laccolite of monzonite porphyry, half a mile long and extending well up the mountain ridges, containing—if everything assaying over 1.5 per cent copper is considered as ore—over two hundred and fifty million tons.

The overlay of the Highland Boy sulphide deposit was also found to be largely impregnated with copper, and this led Mr. Newhouse to acquire large holdings adjoining, but not included in the combination owning that mine, now known as the Utah Consolidated Copper Company. Prospecting on these revealed an enormous lenticular deposit of copper sulphide formed by replacement in limestone, and even this was not the limit, later investigation showing hundreds of acres of old igneous intrusive monzonite to have been impregnated with copper solutions, possibly by the same later eruptive action as caused the replacements.

This forms the property of the present Boston Consolidated Copper Company, and the mountain now being moved as shown in our front page illustration.

Operations were commenced upon the underground sulphides assaying as much as 8 per cent of copper, but it was at first a question whether the higher impregnations could be mined at a profit. Ore carrying as little as 1 per cent had been profitably mined at the Atlantic in Michigan, but that was native copper, whereas the Bingham deposit was all sulphide. On account of the latter being so readily accessible, however, practically no shaft sinking or pumping being required, it was very cheaply mined, and with the present stripping methods breaking enormous quantities of rock at very low cost, a handsome profit over mill and smelter costs is shown.

The solid sulphide ore mined below still pays for the operations on the mountain top, ore being stoped



A great smelter at Garfield, Utah, built especially to treat the ores excavated at Bingham Cañon.

MOVING A MOUNTAIN IN UTAH.

from three underground levels in a deposit at some places 100 feet wide. The ore is discharged from the upper to the lower levels by chutes, and from the lowest directly into cars of the "high line" of the Rio Grande Western which convey 750 tons daily from the Boston Consolidated to the smelter of the American Smelting and Refining Company at Garfield.

The stripping operations at the top of the mountain began with the removal of waste rock overlying the enriched monzonite, the ground having been leached of its values to a depth varying from 30 to 60 feet. This waste is carried round the mountain and dumped on the far side, where the ore body lies lower and could not be eventually mined by removal of the overlay. Now, however, sufficiently rich ore to be sent to the mill is being stripped in the same way and sent down by the tramway shown in our illustration, the whole of the rock exposed by each blast being carefully sampled and assayed and sorted accordingly.

For the stripping operations five steam shovels were first sent up the mountain by a specially built railroad with numerous switchbacks.

The hilltop is laid out in four benches from 40 to 120 feet high, the highest bench being kept farthest back so that rock blasted there does not fall upon and impede the tracks upon the bench below. Well drilling machines are used to drill 5-inch holes 30 feet apart in a line as far back from the face of each bench as the explosive will break. When the holes reach the level of the bench below they are pumped out and "sprung" with 25 sticks of 40 per cent dynamite, again with 50 sticks, and sometimes again with 75 or more. This makes a chamber at the bottom of the hole large enough for the breaking charge, which is from 20 to 60 boxes of powder per hole. A row of holes is fired simultaneously by electricity, and the whole face of the bench is moved and shattered so that it can be handled by the steam shovels. On the average 2.8 tons of rock is broken per pound of explosive used, and 0.68 ton per foot of hole drilled. Masses too large to be handled by the shovels are drilled with percussion or air-hammer drills and split up.

Each of the shovels is of 90-ton capacity with a 5-ton dipper. Two trains of wooden dump cars attend each shovel, and the latter fill the 4-ton cars at the rate of about one a minute. Four shovels, each working two shifts of ten hours, have handled 14,000 tons in a day, making 175 tons per hour each. The cost of excavation has been as low as 12 cents per ton of ore delivered in the cars, including explosives, labor, and shoveling.

The ore selected to go down to the mill is dumped by the cars in a 100-ton receiving bin at the top of the incline shown in our illustration, which feeds it into the 12-ton skips of a balanced gravity tramway. The latter has two pairs of tracks 2,100 feet long descending the hillside at a gradient varying from 23 deg. to 27 deg. The skips discharge about 150 tons per hour into the steel-tank receiving bin at the foot of the tramway, having a capacity of [illegible]000 tons, which discharges directly into the railroad cars of the high line.

The smelter at Garfield shown in our illustration was built especially for treatment of the ores of the Boston Consolidated Utah Copper Company and other mines of the neighborhood, after contracts had been made with them providing for a certain constant supply.

On account of the mountainous and irregular nature of the ground, aerial cable tramways are found to be the cheapest means of transporting the ore in some cases, that of the Utah Apex mine being shown in one of our illustrations. In these buckets suspended from rollers travel upon a fixed cable supported on towers, the buckets being clamped to an endless traveling cable passing round drums at the head and foot of the line, the weight of the loaded buckets descending carrying up the empties on the other side.

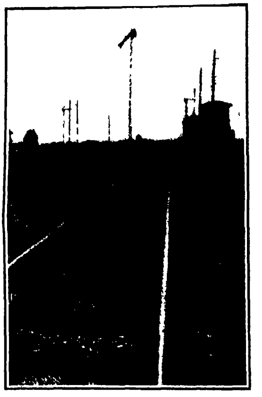
From present indications only the price of copper can limit the alteration of the horizon in Bingham Cañon, the time being measurably distant when the gulches will be filled up with waste rock and the mountain top reduced to about their level.

A NEW AUTOMATIC ELECTRIC SIGNALING SYSTEM FOR RAILROADS.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

An important development in automatic signaling for railroads has recently been introduced in Great Britain by the Great Western Railroad, the foremost trunk line in the country. Despite the elaborate nature of the block system, and the strict rules laid down in connection with its working, several accidents have recently occurred in the country owing to the ordinary semaphore signals, especially those at the distant point, being inadvertently overrun by the engineer, more particularly in the case of express trains, the mishap being due to the signals being obscured by fog, snow, or rain. Notwithstanding the excellence of the block working, this dependence upon the human element has proved its weakest link. The Board of Trade department of the government, which is responsible for insuring the safe operation of railroads, has long advocated the adoption of an automatic signaling system whereby the engineer is given on his engine not only a visual but also an audible indication of the condition of the section upon which he is entering at any time, since it is realized that the momentary occupation of the engineer's attention to any other detail on the locomotive at the instant of passing a signal might easily jeopardize the safety of his train.

The Board of Trade officials have subjected the latest idea, which has been adopted by the Great Western Railroad, to the most severe and exacting tests, and although it is valuable as an auxiliary to the ordinary semaphore, it can be safely operated without the latter, and as a result of their investigations have conceded to this railroad permission to remove their semaphores and operate a section of their track solely upon this new system, which concession is the first that has ever been granted to any English railroad, and consequently marks an important era in the safer working of railroads.



Section of track provided with central ramp.

Rear view of locomotive, showing contact shoe.

A NEW AUTOMATIC ELECTRIC SIGNALING SYSTEM FOR RAILROADS.

The system adopted is entirely electric, there being no mechanical parts such as triggers to come into contact, so that no concussions can result which might imperil the durability of the invention. Upon the locomotive is carried a downward projecting shoe, similar in design to that utilized upon street railroad cars to collect the current from the feed rail, and this shoe comes into contact with a long section of ramp laid between the tracks, thereby establishing electrical communication, and notifying the engineer in the cab both visibly and audibly whether the section of road he is entering is blocked or clear. These audible signals comprise a steam whistle or siren, which is sounded to notify that the signal is at "danger," while "line clear" is signified by means of an electric bell. Either of these signals, when once set in action, continues to sound until it is stopped by the engineer, so that the latter must inevitably realize the condition of the track by stopping the whistle or bell, thereby accepting the warning extended to him. Both signals are given by the operator in the signal cabin to the engineer without the movement of any apparatus on the track, this latter constituting a fixed ramp. Moreover, should there be any breakdown in the electric circuits a danger signal is conveyed to the engineer whether the road is clear or otherwise, so that his attention is drawn to the fact instantly. Also, should the insulation of the ground apparatus be broken by the presence of grease, dirt, snow, water, etc., so that the electric circuits cannot be connected, the danger signal is instantly sounded. In addition to the siren and electric bell placed in the locomotive cab, there is an indicator extending corresponding visual signals, the danger signal being represented by the word "danger" printed on a red ground appearing in the glazed aperture of the indicator, while "line clear" is represented by a clear white space. It will be realized therefore that much of the value of the system lies in the fact that the danger signal is operated whenever any untoward circumstance exists, such as apparatus breakdown, disturbed insulation, etc., whether the line be clear or *vice versa*.

Immediately beneath the cab of the locomotive is placed the shoe (in the accompanying photograph the tender of the locomotive has been removed to show its position), which comes in contact with the fixed ramp, during the passage over which it is lifted. The normal position of this shoe is 2½ inches above rail level, but when passing over the ramp, owing to the latter projecting some distance above rail level, it is raised about 1½ inches. This contact shoe is of stout construction and is capable of adaptation to any type of engine. The contact face is 7 inches wide and it is case-hardened. There is a strong spiral spring provided which insures the shoe returning to its normal position directly it leaves the ramp. This shoe is insulated from the mass of the engine, and the caution signal is operated by the disruption of a local electric circuit on the locomotive. In its normal position the shoe serves to complete this electrical circuit, but directly it is raised, as when passing over the ramp, and even if only raised ⅛ inch, the circuit is broken. The result of this circuit interruption is that a steam whistle is brought into action which has previously been held closed by the circuit.

In connection with the whistle and bell signals, an indicator board is attached at the side of the cab. There is a large slot before which appears the notification "Danger" upon a red ground when the signal is against the engineer, giving way to a blank white space when the line is clear, these two notifications coinciding with the whistle and bell signals respectively. Thus the engineer is given a clear positive visual warning in addition to the positive audible signals. The push button shown on the side of the indicator is that by which the engineer stops the ringing of the bell, and the lever the means by which the steam whistle is closed. The ramp is laid down at the point where the distant signal is desired to be given, and, if the semaphore is still to be retained, is installed beside it, centrally between the running rails. It comprises a bar of T iron mounted and insulated upon a timber base, and is bolted to the cross-ties to insure rigidity. Upon tracks upon which fast-running trains are maintained the ramp is made 60 feet in length; while for branch lines a 40-foot length has been found to be sufficient.

* * *

The cause of the disappearance of rust from iron bars, etc., used in the erection of reinforced concrete structures, has been traced by Rohland, in Stahl und Eisen, to the presence of acid carbonates and sulphates in the cement, these salts dissolving the iron oxide and leaving the metal bright. The cement in setting absorbs carbonic acid from the air, thus forming the necessary acid carbonates, and experience has shown that the de-rusting process is effected while the concrete is setting and commencing to harden. This discovery affords an additional guarantee for the safety of reinforced concrete structures, inasmuch as the metal is protected from rusting by the alkaline reaction of the cement during the mixing process, and any rust on the bars is removed by the action of the acid carbonates at an early stage in the erection of the structures.

THE VESSEL THAT ACCOMPLISHED THE NORTHWEST PASSAGE.

BY J. MAYNE BALTIMORE.

The Norwegian seventy-five-foot sloop "Gjöa," which is famous the world over for having been the first and only craft to have threaded its way through the Arctic Ocean from the north Atlantic to the Behring Sea, is now the property of the city of San Francisco. Capt. Roald Amundsen, the noted Arctic navigator, sailed from Christiania, Norway, with a crew of seven in the year 1903, and after nearly three years he succeeded in reaching Nome City by way of the Northwest Passage. From there he sailed his little vessel out into the Pacific, and thence down the coast to San Francisco harbor Later he returned to Norway, leaving the "Gjöa" at the Mare Island navy yard. The little craft was turned over to the Norwegian consul at San Francisco by his government, with instructions to make whatever disposition of this historic vessel he deemed best. The consul finally concluded to present the "Gjöa" to the city of San Francisco in behalf of the Norwegian government, to be preserved as a relic and souvenir of the feat of Capt. Amundsen in making a voyage through the Northwest Passage.

THE "GJÖA" BEACHED AND ABOUT TO BEGIN ITS "INLAND VOYAGE" TO GOLDEN GATE PARK.

The city authorities gladly accepted the gift of the famous old craft, and decided to place the vessel in a conspicuous position at the extreme western confines of the Golden Gate Park just bordering on the ocean beach.

The "Gjöa" was fitted into a cradle of wood, and loose dry sand filled in all around up to the waterline. The work of hauling the old sloop out of the sea up the beach for a height of more than 40 feet and several hundred feet across the big boulevard to the point where it is mounted in permanent position proved a very heavy and difficult task of engineering. Several days were required to accomplish this work

The total weight of the empty hull of the "Gjöa" is estimated at 300 tons. The total length over all is 75 feet, length of waterline, 65 feet, beam, 16 feet, depth of hold, 16½ feet. The "Gjöa" was not primarily intended for Arctic navigation When purchased by Capt. Amundsen, the vessel was reinforced with stout wooden and iron beams and sheathed with an outer layer of 2-inch planking and fitted with a petroleum engine of 39 horse-power and a two-bladed propeller However, sails were depended upon as main motive power

A TAME NAUTILUS.

BY CHARLES F HOLDER.

The accompanying photographs show a paper nautilus which was so tame that I could handle it with impunity The animal was brought to me without a shell, and I provided it with one.

The beautiful animal seized upon it with all the eagerness of a homeless hermit crab, occupying it at once. When alarmed it would crouch low, its entire body and tentacles drawn into the shell; nothing but the green eye to be seen peering over the edge. Then, when satisfied that all was well, it would gradually come out, changing tint and shade of blue all the time, presenting a most interesting spectacle. Now the two large shell-forming arms would creep out and slowly envelop the shell, until it was entirely covered by the speckled blue mass. The animal would do this even when I held the shell. The animal did not display any fear, and would throw its tentacles about my fingers, and even leave the shell and permit me to handle it. This is well shown in the illustration, where the animal is leaving the shell which I am holding. Its big blazing silver shell-making tentacles are being thrown over my hand, while the other arms are toying with the weed at the bottom.

The dark spot in the center is the mouth, or the black mandibles surrounded by a white circle of muscle. In another view the animal is seen entirely out of the shell, its mouth near my thumb one long tentacle thrown across my fingers, while the big spreading tentacles of silver and blue are being waved aloft like brilliant Venetian banners The eye is shown as a pure white spot just below the mouth and near the large gill openings Below this hangs the bag like body When I withdrew my hand the nautilus fastened itself to the glass sides of the tank and hung a glistening mass of color, scintillating in the light Not one person out of a thousand could even guess what it was. Even teachers of zoology when the shell was taken away, failed to recognize it, and there was some reason as this was the first opportunity they had had to see the animal really alive By placing a cloth over the tank and raising and lowering it the nautilus could be made to change its color

If the broad tentacle is examined it will be seen to have radiations which correspond to those of the shell itself It also bears numbers of glands, and clings tenaciously to any object it may touch These tentacles are the shell makers, and part of the work in shell making was observed in a specimen that had no shell. Resting on the bottom, it held its two shell secreting arms above side by side, in point of fact, they were joined at the base Then from the glands oozed the shell-making secretion and it soon appeared as a gelatinous cast of each tentacle, the exact size of the shell the animal had been inhabiting

SCENES IN THE LIFE OF A TAME PAPER NAUTILUS.

The radiation on the face of the tentacles match the radiations on the shell and one could imagine that gelatin had been pressed into the molds and allowed to harden, and this is practically what is done The two molds (tentacles) are held up close together, the left one forms the left side the right one forms the right side. Then by manipulation they are joined together Indeed the two tentacles have been joined all the time, and so form a mold in which the beautiful shell or egg capsule is made I watched this radiant creature all day and late into the night and the following morning part of the new shell was found a delicate tenuous mass that would gradually harden Hence I believe that a new and large shell can be produced in a few hours and nearly a whole one was made by this animal in the Avalon zoological station between 1 o'clock in the morning and 9

It is given in all the textbooks I believe that the male of the argonaut is a minute animal hardly an inch long This cannot be so in all species I have a male which has a radiant spread of eight or nine inches and is as large as the female The female lives in the shell and deposits her eggs here—yellow masses which hang in the shell I saw her leave the shell and wander about at will darting into it when alarmed and having practically all the habits of an octopus The male of this species is large and might readily be taken for an octopus having its habits The beautiful animal appears at the Southern California channel islands especially Santa Catalina in February and August from ten to twenty shells being found every year Doubtless hundreds come ashore but are deserted and broken

The argonauts that I have kept in confinement three in number were extremely interesting They would eat fish from my hands readily and displayed little or none of the timidity of the octopus When alarmed they would dash away filling the water with ink and propelling themselves by the siphon out of which they sent water with such force that when held above it the stream would go five or six feet through the air I noticed that the octopus tried to use this as a defense as when I moved my hand near its egg cluster it would direct the siphon at me and shoot a stream with such force that it was easy to see that small enemies at least would be blown away

The Grand Trunk Pacific Railway (Canada) has commenced a novel undertaking whereby a record of the growth of the West so far as the railway is a factor in its growth will be kept The official photographers of the company have begun to work on the plan of the company and towns along the line will be photographed each photograph being duplicated yearly so that a continuous record may be obtained and kept of each individual town from the time it sprang up throughout the period of its growth The record kept is expected to be of invaluable importance in years to come

In British Columbia platinum is found in many of the alluvial gold workings where it can be saved as a by product The saving of it in a small way is however attended with so much trouble that it has been practically neglected and no appreciable production made recently

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

BURIAL ROBE.—C I OWEN, New York, N Y The aim of this invention is to provide a construction which will enable collars of different styles to be used with the same grave clothes and which will also enable the collar to be readily attached or detached to and from the clothes and around the neck of the body

Electrical Devices.

ARMATURE J P NICKONOW Evansville Ind The invention relates to armatures of a type suitable for dynamos and motors, the particular purpose being to render the armature strong and durable and especially braced against the influence of centrifugal force It relates to means for improving the circulation of air adjacent to the armature in order to prevent overheating of the windings thereof

ELECTRIC THERMOSTAT - J R CARLENTER Hancock, Mich The invention pertains to electric thermostats the more particular purpose being to provide a construction in which the action is alternative, that is to say either an increase or a decrease in the temperature beyond a predetermined limit will cause an alarm to be actuated

Of Interest to Farmers.

HAY RETAINING DEVICE FOR HAY STACKERS—J O McCAFFEY Fort Morgan Colo In a well known apparatus a series of parallel teeth are pivoted to a head forming part of the stacker frame which rests on the ground Hay is carried up to the stacker and deposited by a sweep rake The teeth of the stacking apparatus are provided with pivoted fingers for retaining the hay deposited thereon said devices being adapted to release the hay when the teeth are raised for throwing the hay backward The invention is an improvement in construction and attachment of the hay retaining fingers

SEED DRILL G W NATION Alliance Neb In operation the framework being drawn through the field the disks which are provided with radial sickle shaped blades stir up the soil and prepare it for being furrowed by furrow openers of the drilling attachment. The rotation of the dropping wheels permits the grain to move in predetermined and regular quantities through shoes into the furrow and the shoes may be adjusted to any position by a handle

CORN HANGER F F SWANSON Galesburg Ill The invention is an improvement in corn hangers for hanging ears of corn for use as seed corn or otherwise Brackets are arranged in pairs and consist of two wires loosely wound at their middle portions side by side around the round part or bearings, usually two full turns with their free ends bent upwardly to receive the ears and when in use the brackets are turned on the round portions to space apart the adjacent arms. It is suspended by a hook.

Of General Interest.

TRESTLE - R J KOCH New York N Y The improvement is in trestles of a folding or knock-down type for general use where such an elevated support is required, and has in view a trestle preferably in the main constructed of sheet metal, providing a relatively strong structure which when disassembled may be packed within a space approximately not larger than the trestle beam

SHIPPING CASE C C HOTCHKISS Great Bend Kan The invention is adapted to various kinds of shipping case devices and relates primarily to the corner connections between the several walls of the case the same being so constructed as to permit of the rapid and convenient assembling and disconnection of such parts and producing when erected, a case capable of withstanding rough usage

SEPTIC TANK A W HUHMAN Staunton Ill The tank is for use in sewage disposal in which the sewage is partly purified by means of fermentation or putrefaction in which the passage of sewage therethrough can be readily controlled which permits it to escape in case the outlets are clogged so that the material backs up within the tank and which is provided with manholes, and manhole covers so that the tank can be tightly closed, while access can be easily had thereto

HATCH A N McGRAY Boston Mass This hatch cover can be securely battened down upon the hatchway to prevent water from entering the hatch if the vessel is laboring in a seaway so that waves break upon deck or to prevent the escape of liquid from within the vessel where a hold section has become filled by accident or serves as a container for liquid in bulk or is filled with liquid for ballast or stability purposes which can be easily manipulated and in which dead space under the deck is reduced to a minimum.

GAGE FOR DEEP SEA SOUNDINGS —J MEI and T JONES JR Galveston Texas. One purpose of the invention is to provide a liquid gage or recorder for deep sea soundings, so constructed that it will contain no moving parts and so that its action is both positive and direct and so that the instrument can be used an indefinite number of times without any delay

BOTTLE WRAPPER E C RINNER, Coshocton, Ohio. The invention pertains particularly to that type of wrapper which is formed of corrugated cardboard or pasteboard. The improved construction tends to distribute the pressure when a number of articles covered by the wrappers are packed in a shipping case.

CEMETERY STRUCTURE—G C SIMPSON West Newton Mass The invention refers to reinforced concrete and provides improvements in cemetery structures, such as mausoleums memorials burial vaults and the like whereby the structure is rendered exceedingly durable and fireproof, can be cheaply erected, and enables the builder to provide any architectural features and an unlimited variety of designs and appearances.

Hardware.

CURRYCOMB —A C DITMAR, Davenport, Wash This currycomb will be substantially self-cleaning that is, it is constructed in such a way that when pressure is removed cleaning devices which are attached to the sides of the teeth will move down toward the points of the teeth in such a way as to clean or wipe them

NUT LOCK —W E FRAZER, Perham Minn. In this invention the object is to provide a device simple and efficient in construction and inexpensive to manufacture which will effectively lock a nut in place on the shank of a bolt against accidental displacement, and which can be readily loosened by hand.

TOOL-GRINDING APPARATUS - G W RIDDLE, Breckenridge, Mo. A leading feature in this invention is the arrangement of the three hollow legs composing the frame in such convergent relation to the shaft of the grinder proper that one serves as a support for the said shaft and another as a guide and protector for a retracting spring connected with the shaft

SOLDERING DEVICE —F S CHAPMAN Kenton Ohio. The invention provides improvements in means for use in soldering metallic parts and is especially applicable to those joints used in electrical constructions which require a good metallic contact in order to provide against undue resistance to the electric current in the conductors at their point of union

OILSTONE HOLDER —F J BADER Brooklyn N Y and C L CARTER, Salfords, Horley Surrey England In general this invention consists of a relatively long bar provided with a handle and having a tool seat on one face extending in the direction of its length preferably V shaped in cross section and a spring to bind on the inner end portion of the tool and force the tool to the seat adjustable along the length of the member

PROCESS FOR THE MANUFACTURE OF A MIXTURE OF GAS AND AIR FOR ILLUMINATING PURPOSES—F W WOLFF, Berlin Germany This process is for use in the production of a gas and air mixture for illuminating purposes there being a connection with the pipes of a gas work and employing a suction and forcing apparatus which produces and sucks the mixture at low pressure and feeds it at an increased pressure to the consumption place.

Heating and Lighting.

GAS-PRESSURE REGULATOR—J G WILSON, New York N Y This gas pressure regulator is for use in the service pipe between the gas meter and the burners, and is arranged to insure uniform pressure at the burners, to render the regulator exceedingly sensitive, and to prevent the working parts from sticking

DRIER —J M URGELLES, Baracoa, Cuba The drier is intended more especially for coffee and similar materials. It consists of a section oven each section divided into drying compartments, each compartment having a track therein a truck movable over the track having containing drums, with the axes extended through a plate which forms the front of the compartment and carries means for driving the drums steam coils arranged in the compartment under the drums and means for introducing hot air jets over the drums.

MANHOLE AND BONNET FOR PIPES AND FURNACE-CASINGS —E PARMENBORG, Syracuse N Y An object of this invention is to so construct the cover or bonnet for closure of an opening formed in a hot air furnace wall or a hot air pipe that the material removed in the formation of such an opening will be used in the production of a bonnet or cover therefor and thus economize material.

Household Utilities.

STOVE.—F MADSEN Wilbur, Wash. The present invention has for its principal objects the following first, to increase the available radiating surface in a stove second to cause the heated gases to maintain closer and more intimate contact with the metal of the radiating surfaces third, to regulate the output in heat of the radiator

COMBINED NAPKIN RING AND HOLDER W L BARNARD Halstead Kan. The intention here is to provide a ring and holder simple in construction and inexpensive to manufacture which can be used to hold a rolled napkin when the latter is not in use, or which can be converted into a holder for securing the napkin in position upon the body of a person during meals.

STOVE.—E C COLE, Chicago, Ill. The invention comprises a plurality of series of fire bricks arranged one series above the other, and a series of spaced apart vertical draft columns between the bricks and extending across the joint between the series of bricks, and provided with openings, the columns operating to hold the bricks in place.

CHAIR —I MASON, New York, N Y This chair is capable of being converted for various uses. The invention consists in a device comprising an arm chair having a removable seat that can be so fitted to the arms and back as to cover the intervening space and provide a table bounded by the upper contour of the chair

Machines and Mechanical Devices.

STAVE-CUTTING MACHINE.—M. C. THOMSCHMIDT, New York, N Y The object of this inventor is to provide a new and improved stave-cutting machine, arranged to quickly and accurately give the desired shape to the stave both as to the longitudinal contour of the side edges as well as the bevel thereof and without requiring handling of the material.

AUTOMATIC LOCK FOR HOISTING APPARATUS —R. M RODGERS, New York, N Y The invention appertains to an improved locking device for hoisting appliances, more especially dumbwaiters, in which relation it automatically operates under the tendency of the load to lock the car in any position of its movement immediately after the pull on the hoisting wheel ceases.

GUIDE ATTACHMENT —H HOLMES Duffey Cal The main purpose here is to so construct the guide that the cable may be readily removed therefrom without disassembling the device and a further important object is to so connect the body of the device to the stationary support that it may freely rotate in respect thereto but cannot become detached therefrom

GOVERNOR —G H WILSON, Spokane, Wash The object of the inventor is to provide a new and improved governor, for use in automatically checking the speed of automatic fire escapes and other machinery requiring a steady uniform motion When the machine again runs at a normal rate of speed the piston is returned to its normal position by the action of a spring

WASHING MACHINE. J D WILLIAMS Clay City Ky In this case the purpose is to provide novel details of construction for a washing machine, which embody reciprocating rollers with a corrugated spring pressed plate in the suds box, and other novel features that co-operate and together afford a simple very effective and convenient machine

LOCK FOR DAVITS — W J RYAN and L TANNING New York, N Y The invention refers to davits and associate mechanism for handling small boats on shipboard. The invention comprehends a davit including a staff which may be turned for the purpose of handling a boat the limits of the turning being adjustable at will

DISPENSING MACHINE. P C PETERSEN, Perth Amboy N J The invention is an improvement in machines for dispensing cigarettes and matches or similarly shaped articles and has in view an apparatus to be actuated by a check or coin-controlled mechanism and which will deliver a cigarette and a match at each operation.

FLYING-MACHINE —W H MARTIN Canton Ohio. Two general principles are comprehended in this invention one serving to effect an automatic adjustment of an aeroplane to such an angle to the horizontal as to cause it to have a buoyant tendency from the resultant upward pressure against its lower sides. The other serving for the automatic balancing, or self righting quality of the aeroplane as against tendency to dip sidewise about its axial line of flight

ELEVATOR W T LONG, Sumner Wash. In this elevator Mr Long provides a carriage a frame being provided to travel in guides in the carriage a yoke being disposed in the frame two clamps being pivoted to the yoke, the clamps being also pivoted to the frame, the means being provided to limit the movement of the yoke and to move the frame relatively to the carriage

OIL-FEED FOR DRILLS —M GALLOWICS, New York N Y The object of this inventor is to provide means for feeding oil through the bit of the drill to its cutting point. More specifically the device embodies an oil head which is formed above the drill chuck, and this oil head is provided with means for controlling the flow of oil from the reservoir through the oil duct which is formed longitudinally in the drill.

PUMP —F FOLEY, Crowley La The valve in this case comprises a series of members arranged in superimposed position, adapted to seat, one above the other, effecting closing position and at the same time being adapted to lift or be lifted to opening position. The valve is designed for use upon a pump piston having an opening vertically therethrough

FEED MECHANISM FOR TUBE CUTTERS. - W CUSHING, Claysville Pa The object of the invention is to provide a feed mechanism for feeding a mandrel used for forcing the cutting wheels of the revoluble cutter outward in a gradual but positive manner to insure the proper cutting of the cutting wheels without danger of injury to the same.

Prime Movers and Their Accessories.

VALVE-GEAR.—T O'BRIEN, New York, N. Y More particularly stated the invention comprises a construction whereby certain movable valves actuated periodically by push rods are readily disconnected from the latter and from their housings, and thus removed from the engine and easily replaced within the engine by reversing the steps necessary to remove it.

Railways and Their Accessories.

COMPRESSED-AIR SIGNAL —R ARMSTRONG, Victoria, British Columbia, Canada. Particularly stated the invention comprehends a whistle operated by compressed air from the signal pipe, and valve mechanism controllable by variations in the pressure of air within the signal pipe for controlling automatically the supply of air to the whistle.

DELIVERY APPARATUS.—H B MURRAY, JR., Portsmouth Ohio. More particularly the invention relates to apparatus adapted to be used in connection with railroads or the like, for delivering messages and dispatches. It can be used for delivering messages from a car to a point alongside a track or *vice versa*, and is so constructed that one or more messages can be delivered without the necessity of resetting the apparatus.

RAILWAY-CUSPIDOR.—W HILL, Albany, N Y The invention relates to certain improvements in cuspidors especially designed for use in railway cars or other vehicles, and one object is to provide a device which may be readily moved about to bring it to the desired position and which will automatically drain to the exterior of the car

BOX-CAR DOOR —W T ANFIELD, St Louis, Mo. The invention is an improvement in the class of doors for box freight-cars and other inclosures, which are adapted to roll parallel to the side of the car or inclosure, for covering or uncovering the doorway For convenience in moving the door it is provided with a handle arranged adjacent and parallel to the curved or contact portion of the door-rail

Pertaining to Recreation.

DEVICE FOR ASSISTING IN THE SHOOTING OF MARBLES.—H O HUGHES Slatington Pa The aim in this case is to provide a cap which is adapted to be disposed on the thumb of the player, the cap having an outwardly disposed stud intermediate of its ends, which is adapted to engage a marble when it is held between the finger of the player and the cap covering the player's thumb

Pertaining to Vehicles.

BRAKE FOR VEHICLES - A P PEABODY, Camp Verde Ariz. Ter The inventor provides a construction for a brake wherein the wearing shoe may be quickly and readily replaced; provides a holding device for securing the wearing shoe to the brake which will not become loosened and provides a construction for securing the wearing shoe to the brake which is strong, durable and simple

VEHICLE WHEEL.—L INGRAM and C M. HART, Amityville N Y By this invention the inner tube of an ordinary pneumatic tire may be eliminated and a substitute support the wheel and hold the outer casing in extended position A plurality of cylinders and pistons within the tire are so mounted and disposed as to resist not only pressure radially of the wheel, but also side thrust or diagonal strain

SPRING WHEEL —F N GINN Little Rock, Ark. The invention is especially useful in connection with automobiles motor trucks, and the like. The wheel has resilient means for absorbing shocks from the irregularities of the road, and thus obviates the use of the pneumatic tire and the objections incident to such use

WIND-SHIELD —E FLAGG, New York, N Y A wind shield constructed in accordance with this invention and formed of two sections, one of which is foldable to a position adjacent the other section, may rely solely upon the action of gravity to retain the movable section in either of its two positions, which is not ordinarily possible with a shield held in a vertical position

VEHICLE WHEEL.—D I PAISNER, Chelsea, Mass. One object here is to provide a vehicle wheel with two rims which are separated and held normally in their relative positions by springs and guides, which will not only permit the outer rim to move toward the inner rim and thus furnish the resiliency desired, but will also permit the outer rim to rotate slightly, relatively to the inner rim and thus furnish additional resiliency

STEERING MECHANISM—A MAUKSCH, near Tabor S. D This mechanism can be used with the usual steering knuckles found on automobiles, so as to bring about a greater displacement of one of the two steering wheels than the other The purpose of this is to displace the wheels so that their axes of rotation will intersect in the plane of one of the hind wheels. In this way the turning of the vehicle is made to take place about that hind wheel as a center

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

NEW BOOKS, ETC.

Die Flugmaschinen Theorie und Praxis. Berechnung der Drachenflieger und Schraubenflieger Von Georg Wellner, Maschineningenieur, Hofrat, Professor i R. Mit 100 Abbildungen und 2 Tafeln Vienna A. Hartleben, 1909

The author of this book has had about thirty years' experience in the solving of aerodynamic problems. As a general rule, aeronautical works are either *entirely* practical or purely theoretical In other words, they either simply describe machines that have been actually constructed, or else set forth with the aid of complex mathematical formulæ the theoretical problems involved in aerial flight. The book before us is unique in so far as it is a compromise It is both a practical and a theoretical treatise As to mathematics, the author has purposely avoided the usual analytical method of discussion, which provides for all contingencies and which considers not only uniform horizontal flight but accelerated flight and flight on an inclined plane and has concerned himself chiefly with the synthesis of convenient and easily understood equations for those simpler cases of aerodynamics which agree fairly well with practice Therefore, not a few mathematical formulæ will be found in the book. Nevertheless, the work may be regarded as a semi popular treatise Approximations and abbreviations have been adopted perhaps too liberally but inasmuch as the aim of the author seems to have been clearness of expression and a simple explanation of the principles of dynamic flying, his course seems to be justified An excellent discussion of the relative merits of aeroplanes and helicopters or screw fliers will be found in the work On the whole the tone of the book is healthy It is free from that *exaggerated optimism* which has led the public to expect more from the future of artificial flight than past failures would seem to justify

A History of New York Shipyards By John H Morrison, author of 'A History of American Steam Navigation" New York William F Sametz & Co 8vo, 165 pp, 20 ill Price, $2 50 net.

The name of John H Morrison as the author of anything connected with the history of shipping particularly in New York city and vicinity is a synonym of great accuracy and thoroughness of research and these qualities are evident in the compact work before us In his 'History of American Steam Navigation' Mr Morrison has given the public a very exhaustive summary of the ships built and their subsequent performances Of equal value and interest is the story of the New York shipyards in which these vessels were built It was only during the later history of colonial times that vessels began to be built in this city for the coastwise and the West Indian trade and the material for the history of the shipbuilding of those days is very scanty After the signing of the treaty of peace with Great Britain the shipbuilding industry began to show indications of its subsequent great activity which became pronounced after the monopoly of steam navigation on our rivers was removed in 1824 Then came the building of the ocean and coastwise steamships and later still of the justly celebrated clipper ships. It was not until the close of the civil war that a marked decline began to occur in the shipbuilding of New York city The work opens with a survey of the colonial period followed by a chapter which carries the story to the year 1820 and contains an interesting account of the early American New York ships and shipbuilders including the 'Clermont' and its constructor Charles Browne who, by the way was born in London and served for some time in the British dockyards Subsequent chapters deal with periods of large development in shipbuilding the strikes of shipyard employees and the formation of trade unions, the famous 'Mechanics Bell" whose purpose it was to give regular notice when to commence and when to quit work the new era of ocean steamships, which culminated in the magnificent clipper ships of worldwide fame, the launching of vessels and launching disasters high water in wooden shipbuilding a most interesting chapter containing new information about the yacht 'America" and the records of prominent American clipper ships and finally, a chapter on the decline of wooden shipbuilding This is a most excellent work upon a too-much-neglected subject

Inventions, Patents, and Designs By G Croydon Marks. New York D. Van Nostrand Company, 1909 16mo, 116 pp. Price, $1

In this book Mr Marks has printed in full the British Patents and Designs Acts of 1907, and has in connection therewith devoted many pages to a popular discussion of the questions which patent solicitors are continually required to answer In this way much information is compiled in convenient form for reference.

A Guide to the Country Home. By Edward Kneeland Parkinson. New York The Outing Publishing Company, 1909 12mo, 156 pp. Price, $1

This well printed little book deals with Choosing the Home, Winter Planning; Tools, Their Cost and Use, What Shall We Raise; Live Stock—the Horse; Cows, Their Cost and Care; Swine, the Curing of Hams and Bacon; Fowls, Their Care, Cost, and Price; Crops and How to Plant Them, the Orchard; the Market Garden; the Kitchen Garden; Bees, Trees, Lawns, and Shrubbery and the Harvest The illustrations are printed on woodcut paper and are inserted.

Legal Notices

60 YEARS' EXPERIENCE
PATENTS
TRADE MARKS
DESIGNS
COPYRIGHTS &C.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway New York, or 625 F Street, Washington, D C, in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO, 361 Broadway, New York
Branch Office 625 F St, Washington D C

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending October 5, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Adding machine, R. L. Burd	936,087
Adjustable stand T L Bacon	935 730
Advertising device F Kharas	935 963
Aerial railway, Dublin & Carlson	935 780
Aeroplane A W Reinoehl	935 882
Air compressor F W Gardner	936 114
Air ship A E O Lubke	936,141
Alloy and its production A J Rossi	935 861
Annealing or other like apparatus W R Kinnear	935 703
Annunciator, electric A J Smith	936 015
Automobile protector D F Armstrong	936 075
Axes combined wedge and balancing weight for G W Wallace	935 712
Bag filling and sealing machine W Rulison	936 109
Bag folding machine T M Avery	935 729
Bait artificial, F O. Howe	935 657
Baling press, J W Burkett	936,216
Balls of cast metal making hollow A Casey	935 741
Bank note tester I Cohen	935 963
Barbers chairs, paper server for C Pfanschmidt	936 030
Bathing suit H O Nets	936,021
Baths machine for dipping articles into fluid Dill & Marsh	936,238
Bearing for vertical shafts ball S S Eveland	935,848
Bearing roller side, J M Coleman	935 893
Bed folding, J McLeland	935 921
Beer dealcoholizing, F J Prihyl	935 814
Beer skimmer L F Martin	936,005
Belt controller and tightener M J Davidson	936 004
Belt holder A A Felix	935 840
Beverages apparatus for carbonating and dispensing Paris & Millward	935 858
Bill book, C J Kortz	935 897
Binder loose leaf J P Mentzer	935 767
Bird cage and the like G M Porter	936,032
Blasting cartridge, T Turton	936,102
Bleaching cleansing and sizing compound S. A Flower	936 228
Block See Twyer block	
Block signaling system electric Meschenmoser & Kinnan	935 768
Boat paddle C O Richardson	936 165
Bodkin E Caw	935 638
Boiler W A Nixon	936 023
Bolster H F Pope	936,160
Book duplicate sales, E. K Bottle	935,774
Book triplicating, H P Brown	936 084
Boot and shoe machinery Jack Evans & Taylor	936,242
Boring machine feed mechanism A Fray	936.110
Bottle and other receptacle milk C Marthinson	935 709
Bottle cap non refillable W F A Hoyens	936,082
Bottle capping machine milk D R. Yard	935 879
Bottle closure W R Warner	936,002
Bottle non refillable J G R. Bloomer	935 687
Bottles, case for vacuum or other N Goldberg	936 119
Bottling machine, rotary A A Pindstofte	935 925
Box J J Mitchell	935 674
Box fastener S. Whitehall	935 872
Bracket F E Walden	936 061
Brake attachment automobile J H Reifsnyder	935 937
Brake equalizer, W G Ransom	935 939
Brake hanger W S Adams	935 831
Brake shoe adjuster O S McCurdy	935 804
Brush electric, Bacon & Meller	936 209
Brush holder R. Nelson	936,150
Bucket and lid holder sap A. J Milks	935 760
Buckle L L. Thomas	935 706
Building construction studding clip for M Rittler	936,167
Cabinet for dispensing toilet paper A H. Scott	936,047
Cake coating machine Harton & Creller	935,075
Calipers O. F Olson	936,024
Can opener C B Rigg	935 820
Caoutchouc gutta percha and similar substances, apparatus for washing F Kempter	935,840
Car body bolster, H F Pope	936,159
Car coupling W. H. Schroeder	936,046
Car door D S. Bailey	936,209
Car fender A J Thornley	935 929
Car freight, E V Sage	936,043
Car passenger, F H Lincoln	935 859
Car, passenger, H Rowntree	935,689
Car railway R. A Barber	935 683
Car railway C. L. Schwartz	935,686
Car replacer Heath & Howard	935,845
Car seat railway, Smith & Banford	935 700
Car turnstile Fulton & Smith	936,112
Car wheel W. A Church	935,969
Car wheel aligning means, A G Olson	935,924
Carbureter, L W Silberschmidt	935,686
Carbureter, W. K Bramhall	935,682
Carbureter, W G. Westaway	935,694
Carbureter, G T Glover	936,118
Card attaching device F E. Morril	936,145
Card exhibitor Kilmer & Henning	936,277
Card filer tightener A A Cole	936,218
Carpet cleaner sanitary A J Meier	935 919
Cash register E. H Church	935 840
Cash register W H Muzzy	935 677
Cash register and money changer combined C A Grimm	936,122
Casket, A Malinovsky	936 008
Cattle guard D A Prendergast	935 813
Center tube stem machine W N Parker	936,153
Chair and couch combined, C L. Pulrith	935 861
Chair attachment, M A. McClelland	936,017
Churn E. A Franklin	935 902
Churn stand and power W M Bates et al	935 834
Cigar perforator M F Hall	935 973
Cigarette tipping machine, S Palmowsky	936,026
Cigarette tubes making G Nast	936,019
Clamp J H Umpleby	936 195
Clamp, I M. MacKackie	935 670
Claw bar M Waters	935 714
Cleat joint S Whitehall	935 871
Clock geographical J B Olinger	935 800
Clock nickel alarm E E Stockton 936 053	936 054
Clothes line attachment J H Thomas	936,058
Clothes pounder L E Van Landingham	935 940
Clothes rack folding E. M Blanck	936 080
Clutch H E Coffin	935 644
Clutch friction W A E Henrich	935 900
Clutch friction G Tuckfield	936 190
Clutch mechanism V J Emery	936 102
Coal separator N Mowery	936 015
Comb rack A Vance	936,190
Compound gasoline engine L C Burton	935 740
Compressor W H Miller	936 143
Concrete mixer M J Demorest	935 784
Concrete mixer L W Cargill	935 891
Concrete molding machine J A McNamara	935 678
Concrete tile molding machine D Fuhrer	935 904
Condenser F J Newton	935 924
Conveyer gravity L D Logan	935 669
Conveying apparatus, Adkins & Lewis	935 631

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. **In every case it is necessary to give the number of the inquiry.** Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

$100 CASH for information that will lead to the establishment of any desirable factory at St. Croix Falls, Wis. 17,000 developed horse power going to waste, factory sites practically free. Low taxes, ideal labor conditions, splendid residence section, 40 miles from Minneapolis and St. Paul (500,000 people). All advantages fully explained in new "descriptive folder," free. Write us the suggestion with particulars so that we can interest and finally locate the factory and you will get the cash. St. Croix Falls Imp. Assn., Box [illegible], St. Croix Falls, Wis.

WILL FURNISH capital for promoting good patent, franchise for public utility or other good enterprise. Must come well recommended. Address F. L. Gallagher, Prudential Building, Newark, N. J.

Inquiry No. 8984. Wanted to buy nickeloid for buttons.

MANUFACTURERS, CAPITALISTS. I will sell outright or manufacture on royalty a most valuable invention. For full particulars, address M. H. Schultz, Southampton, N. Y.

Inquiry No. 9018.—For manufacturers of "Weil's Electro-Catalytic Sparking Plug."

PATENTS FOR SALE

FOR SALE.—Valuable hoop-shaving patent, improves quality and greatly reduces cost of manufacture. For further information and particulars, inquire Room 1911, 11 Pine Street, New York.

Inquiry No. 8969.—For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

FOR SALE. Patent No. 912,457. Improved oarlock. Simple, can be made cheaply, large demand, best oarlock out, cheap for cash. Royalty considered in U. S. and Canada. C. Rostman, Friday Harbor, Wash.

Inquiry No. 8973.—Wanted the address of Worthington Boiler Co.

FOR SALE. Patent No. 939,387. Instant adjusting wrench. Best monkey wrench ever designed. Will sell very reasonable or manufacture on royalty. A good opportunity. Address Box 110, Newport News, Va.

Inquiry No. 8986. Wanted the address of the Cohendet Motor Co.

FOR SALE. Valuable hose-clamp patent for air-brake and steam hose used on railway cars, and for any use where a superior clamp is required. For further information and illustrations address H. B., P. O. Box 566, Rochester, N. Y.

Inquiry No. 8987.—Wanted the manufacturers of the Van Winkle, Woods & Sons, and the Weber power meters.

FOR SALE. Self spinning top. Mechanism all inside; will spin five minutes with one winding. Will sell outright or on royalty. U. S. Patent 897,467, August 27, 1908. T. N. Reed, Ennis, Tex.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

FOR SALE. Patents Nos. 482,977 and 494,803, one or both. Wireless battery connector. Up-to-date, neat, compact, reliable, cheap to manufacture. Or part cash and royalty. Address Geo. C. Warren, Sumter, S. C.

Inquiry No. 8996. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE. Patent No. 904,872. An improved marble shooter. To fill a long felt want. The patentee has no funds to promote it. For particulars address H. O. Hughes, 29 Willow Ave., Slatington, Pa.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

FOR SALE.—Canadian Patent No. 120,685. An improved churn. Simple, quick and easy to clean and operate. Good seller and money maker. Act quickly. Wm. Deacon, 119 Osborn Street, Winnipeg, Canada.

Inquiry No. 9010.—Wanted to buy a "Rector Help-a-Phone."

FOR SALE.—United States, Mexico and Canada patents for the De Hymel water lift. Great discovery for lifting water from streams, shallow or deep wells. Address De Hymel Waterlift Co., Riverside Building, San Antonio, Texas.

FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads 4 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9012.—Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

HELP WANTED

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The National Co-operative Real Estate Co., Suite 378, Marden Building, Washington, D. C.

Inquiry No. 9011.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

EDUCATIONAL.

CIVIL SERVICE EMPLOYEES are paid well for easy work; examinations of all kinds soon; expert advice, sample questions and Booklet 40 describing positions and telling easiest and quickest way to secure them free. Washington Civil Service School, Washington, D. C.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for reducing salt by a modification of the Bessemer process.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9018. Wanted, the address of parties manufacturing gold plated pens for use in cheap fountain pens.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9021. Wanted to buy a light, small motor not exceeding three pounds in weight, including everything in going order.

Inquiry No. 9023.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Inquiry No. 9026.—Wanted, address of parties who make "Invar" or other metals having a low coefficient of expansion.

Inquiry No. 9027.—Wanted, the address of manufacturers of small wooden articles.

Inquiry No. 9028.—Wanted to buy a washing machine that is run by a coil spring motor.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9030.—Wanted, the address of firms manufacturing a wood fiber bottle and ones made from same material.

Inquiry No. 9031.—Wanted the address of the makers of nonmetallic bowling balls.

Inquiry No. 9032.—Wanted the address of parties who supply carriage and wagon makers with white gum wood blocks for making hubs for vehicle wheels.

Inquiry No. 9033. Wanted to buy machinery, etc., to install a plant for manufacturing condensed, malted and evaporated milk.

Instructive Scientific Papers

ON TIMELY TOPICS

Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER. By Harold Busbridge. An excellent presentation of modern views; fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER. By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT-VISION SPECTROSCOPES. By T. H. Blakesley, M.A. An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865. The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

Price 10 Cents each, by mail

Popular Books

Experimental Science

By GEORGE M. HOPKINS

Revised and Greatly Enlarged. 2 Octavo Volumes. 1,100 Pages. 900 Illustrations. Cloth Bound. Postpaid, $5.00

Owing to the amount of new matter added the book is now published in two volumes, handsomely bound in buckram. Of the additions which have been made, among the most important are: A full illustrated description of ¼ H. P. Electric Motor, prepared expressly for this edition of "Experimental Science"; chapters on Alternating-current Machinery and clear concise Explanations of Wireless Telegraphy and Telephony, Electrical Measuring Instruments, the Electric Clock, the Telegraphone, High Tension Currents, the Nernst Lamp, and methods of measuring the heat of the stars. No other work contains such a fund of trustworthy up-to-date scientific information presented in a clear and simple style. Send for descriptive circular.

The Scientific American Cyclopedia of Receipts, Notes and Queries

15,000 RECEIPTS 734 PAGES

Price $5.00 in cloth

This splendid work contains a careful compilation of the most useful Receipts and Replies given in the Notes and Queries of correspondents as published in the SCIENTIFIC AMERICAN during the past sixty years together with many valuable and important additions.

Over Fifteen Thousand selected receipts are here collected, nearly every branch of the useful arts being represented. It is by far the most comprehensive volume of the kind ever placed before the public.

HOME MECHANICS FOR AMATEURS

By GEORGE M. HOPKINS,

Author of "Experimental Science"

12mo. 370 Pages. 320 Illustrations

Price, $1.50 Postpaid

The book deals with wood working, household ornaments, metal working, lathe work, metal spinning, silver working; making model engines, boilers and water motors; making telescopes, microscopes, and meteorological instruments, electrical chimes, cabinets, bells, night lights, dynamos and motors, electric light, and an electrical furnace. It is a thoroughly practical book by the most noted amateur experimenter in America.

Scientific American Reference Book

12mo. 516 Pages, Illustrated, 6 Colored Plates. Price, $1.50 Postpaid

The result of the queries of three generations of readers and correspondents is crystallized in this book which is indispensable to every family and business man. It should be found on every desk. It is extensively used by government officials. It has been revised by experts. The book contains 50,000 facts and is much more complete and exhaustive than has ever been attempted. It is profusely illustrated with engravings, many of them imparting the information by means of comparative diagrams.

The Scientific American Boy

By A. RUSSELL BOND

12mo. 320 Pages. 340 Illustrations

Price $2.00 Postpaid

This is a story of outdoor boy life, suggesting a large number of diversions which, aside from affording entertainment, will stimulate in boys the creative spirit. In each instance complete practical instructions are given for building the various articles.

The needs of the boy camper are supplied by the directions for making tramping outfits, sleeping bags and tents; also such other shelters as tree houses, straw huts, log cabins and caves.

MAGIC Stage Illusions and Scientific Diversions, including Trick Photography

The illusions are illustrated by the highest class of engravings, and the exposes of the tricks are, in many cases, furnished by the prestidigitateurs themselves. Conjuring, large stage illusions, fire-eating, sword-swallowing, ventriloquism, mental magic, ancient magic, automata, curious toys, stage effects, photographic tricks, and the projection of moving photographs are all well described and illustrated.

By A. A. HOPKINS. 568 pages. 420 illus. Price $2.50

Industrial Alcohol

ITS MANUFACTURE AND USES

A Practical Treatise based on Dr. MAX MAERCKER'S "Introduction to Distillation" as revised by Drs. DELBRUCK and LANGE. Comprising Raw Materials, Malting, Mashing and Yeast Preparation, Fermentation, Distillation, Rectification and Purification of Alcohol, Alcoholometry, the Value and Significance of a Tax-Free Alcohol, Methods of Denaturing, Its Utilization for Light, Heat and Power Production, a Statistical Review and the United States Law.

By JOHN K. BRACHVOGEL, M.E.

528 Pages 105 Illustrations Price $4.00

☞ A special circular describing these books sent on request.

☞ Any of these books sent prepaid on receipt of price.

MUNN & COMPANY, Inc.

Publishers, 361 Broadway, New York

Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS The article tells how a small and simple experimental installation can be set up at home Scientific American Supplement 1551

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ½-H.-P. ALTERNATING CURRENT DYNAMO Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX PINS, AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid to explain the meaning of capillary elevation and depression to serve as a hydraulic tourniquet an aspirator, and intermittent siphon; to demonstrate the ascent of liquids in exhaustive tubes to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1563.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1594.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER Clear diagrams giving actual dimensions are published Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618 A plunge battery of six cells, a two-inch spark induction coil a pair of one-pint Leyden jars, and an inductance coil, and all the apparatus required most of which can be made at home

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained, with the help of diagrams, in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT illustrated with diagrams. Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams, Scientific American Supplement 1624.

HOW TO MAKE A MAGIC LANTERN Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained, with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on **SMALL WATER MOTORS** are contained in Scientific American Supplement 1494, 1559, and 1566.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210,

A WHEATSTONE BRIDGE, Scientific American Supplement 1595.

Good articles on **INDUCTION COILS** are contained in Scientific American Supplements 1514, 1522, and 1527 Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement, 1527

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1562, and 1566.

ANEROID BAROMETERS, Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1554.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

OSCAR WILDE

"A maker of lovely fairy tales, a critic of society whose epigrams had a singular dynamic disintegrating power"

THE FIRST LOW-PRICED

definitive *de luxe* edition of the Works of Oscar Wilde, handsomely bound. The price and terms are so exceptional as to bring the books within the reach of every book lover

AS a philosopher, dramatist, poet, novelist, wit, satirist and master of epigram and paradox, Oscar Wilde was one of the radiant personalities of his age. Whatever we may think of him as a man, we must acknowledge as a writer he has given us some of the most inspiring, kindly and helpful literature in the English language.

THE Novels, Short Stories and Poems include everything Wilde ever wrote and also The Ballad of Reading Gaol previously to be obtained only in a separate volume and several other poems which have heretofore been printed only for private circulation. Wilde was undoubtedly the supreme playwright of his generation. During one season he had four plays running successfully in London and, a few years later, three plays running simultaneously in America.

WHEN this edition, which is absolutely complete, giving all of Oscar Wilde's writings, and is strictly limited, is exhausted, as we think it soon will be, we have every reason to believe that it will be impossible to secure a set of Oscar Wilde except at an almost prohibitive price

MAIL THIS TO-DAY

Big Money In Drilling

Our customers all over the Country are making from $25 to $75 profit a day with the Cyclone Drill. No business offers such big returns for the money invested

Contractors, prospectors, well drillers, find the Cyclone Drill more economical, faster and easier to operate than any other

We make Hollow Rod, Cable and Core Drills, to meet every need

We also make combination machines that will handle any or all of the systems equally well, a machine that will enable you to cover the entire field of drilling

Cyclone Drill

Our Diamondite and Steel Shot Core Drills cut faster and at fraction of the cost of the old diamond drills. We sell Cyclone Drills on an *easy payment plan*. Some of our customers have made more than the price of the machine within one month. Our new traction Gasoline machine—only one made—is of particular value where fuel and water are scarce. Send for our free books on Drilling and let us know in what branch of the work you are interested.

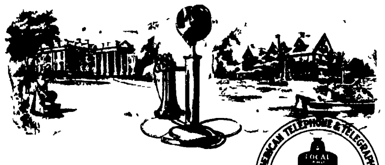
In The Public Service



The President of the United States works for 80,000,000 people all the time

He needs rest and change to keep him fit for his work, and yet he cannot neglect his official duties, he must always be within reach

When Washington was president he rode his horse as far as Mount Vernon and kept in touch by messenger with the affairs of state The President to-day has a wider range and can seek the cooling breezes of the New England coast

The long distance telephone keeps him in constant communication with the capital and the nation

The railroad will carry him back to Washington in a day, but usually he need not make even this brief journey The Bell telephone enables him to send his voice instead, *not only to Washington but to any other point*

The Bell system performs this service *not only for the President, but for the whole public*

This system has been built up so gradually and extended so quietly that busy men hardly realize its magnitude or appreciate its full value

Forty thousand cities, towns and villages are connected by the Bell system, which serves *all the people all the time*

The Bell telephone has become the implement of a nation It increases the sum total of human efficiency, and makes every hour of the day more valuable to busy men and women.

The highest type of public service can be achieved *only by one policy, one system, universal service*

The American Telephone and Telegraph Company
And Associated Companies

Every Bell Telephone is The Center of the System

We Want To Tell You How

You can **save** not only the dealer's profits but his excessive charges for installation and repairs by dealing direct with the manufacturers. You can keep in your own pocket at least one-third the retail price of a heating plant. Let us tell you all about the

Jahant Down Draft Furnace

Only $10 down and $10 per month, with freight prepaid east of the Mississippi River. This wonderful furnace has proven its superiority above all others during the last **30 years**. It will outlast [illegible] It **saves** from ⅓ to ½ in fuel bills because the patented down draft burns hard or soft coal—wood [illegible] without clinkers or clinkers giving full heating value of every particle of fuel. Needs less attention than any furnace you ever saw. A strong Guaranty Bond goes with every Jahant, which allows you ***a 360 days free use of the furnace.*** You run no risk as we supply special plans, full directions and give ***free all necessary tools,*** so that any man who can drive a nail can successfully install a Jahant. No matter what make or system of heating you are considering let us tell you more about the many conveniences and good points of our furnace, its economy, its healthfulness and how you save money. ***Write today for our book.***

Jahant Heating Co., 90 Howard St., Akron, O.

By Rail to Boyville

EVERY boy in the country can easily OWN an Electric railroad. For Christmas time our models of Electric Locomotives, Trains, Trolley Cars, Dynamos, Lamps, Electrical Novelties, etc. make **splendid** presents. Equipped with dry batteries. No acids or liquids. Safe and harmless. Catalog fully illustrated quoting low prices sent FREE.

COOPER'S
REG U S PAT OFF
Spring Needle Knit
UNDERWEAR

Combines COMFORT WEAR and STYLE

COMFORT It is elastic in every direction This makes it fit your skin It yields, but does not stay stretched, for it resumes its shape as soon as the pressure is relaxed The elasticity lasts as long as the garment, and the fabric is the most durable of any It is soft, smooth, and non-irritating.

WEAR All points that have to take extra strain are guarded and reinforced by silk bands, as stays. As the fabric stretches at every stress, it can not tear Each part is as strong as the rest. Washing does it no harm in any of its qualities

STYLE Perfect fit, finest fabric, high-bred finish give the perfection of style.

OUR COOPER'S DERBY & RIBBED UNDERWEAR GRADE DE LUXE TRADE MARK

is on all our goods — our responsibility goes with it. Our machines are patented in nine nations.

Cooper Manufacturing Co.
Bennington, Vermont

A FLOOD OF LIGHT FROM KEROSENE Coal Oil

Burning common kerosene the ALADDIN MANTLE LAMP generates gas that gives a light more brilliant than city gas, gasoline or electricity. Simple, odorless, clean, safe and durable. Is revolutionizing lighting everywhere.

Biggest Money Maker for Agents

Needed in every home. Every lamp guaranteed. Sells itself. Ask our nearest office how you can get a lamp free or apply for agency proposition.

A TALK WITH WILBUR WRIGHT

"No. The next advance in the art of human flight will not be so much in improving the motor as in the practice of high flying Personally, I am perfectly satisfied with our motor, not that one, but the later type, which has been strengthened in the very part where the cylinder gave way just now ' Thus Wilbur Wright. It was in the gathering gloom of an October afternoon, and we were standing alone in the shed which had been built on Governor's Island to house the Wright aeroplane during the late Hudson Fulton Celebration. A few minutes earlier the machine was on its launching ways, with everything primed for an hour-long flight in which Wright had purposed to travel up the East River, over the four great bridges that span it, across Manhattan [illegible] over the Hudson and the Palisades and return to the starting point with a wide detour over the Jersey Meadows and across the Upper Bay We had seen Wright and his mechanic crank the engine by a swift turn of the propellers, had heard the loud explosion and crash, as the forward cylinder tore loose from the crank case, and had seen the wrecked cylinder tear its way through the upper plane and fall at Wright's feet. At the very moment when a million people were lining both shores of the Hudson River, watching with absorbing interest to catch the first glimpse of the author and past master of the art of human flight lo' here was his machine rendered an absolute wreck, and the possibility of a Hudson Fulton flight shut out for good' Under such dramatic conditions of disappointment a Frenchman would have wept. Not so Wilbur Wright. Picking up the broken cylinder he turned to the small group of which the writer formed one, smiled gave an almost imperceptible shrug of his shoulders, and quietly remarked, It is all over, gentlemen "

If there is any appetite for the sensational or melodramatic in Wilbur Wright, he certainly keeps it under masterful control The fact that he had been opposed to the giving of public exhibitions of flight, and that this was the first and only exception that he had made, would for most men have rendered the complete breakdown of his machine a most aggravating disaster Yet five minutes later, when we were alone with him and his disabled air craft, he was perfectly composed, and showed his philosophical estimate of the true significance of the mishap by pointing to the broken cylinder and remarking "This is merely an incident. The machine is an old one that I used at Kitty Hawk The metal was rather light at the point of fracture The defect has been remedied in our later motors '

A few months ago we expressed the opinion in these columns that the element which needed most attention in the aeroplane was the motor and that until the latter had been brought up to the degree of reliability of the automobile motor, the art of flying could not make much material progress Wilbur Wright however does not agree with us. "I have developed my motor to the point at which it has ceased to give me any more anxiety than the motor of an automobile I have run the later pattern of this motor in an endurance test (not of course in the air) for seven consecutive hours, and my machines have made 250 consecutive flights without experiencing motor trouble"

"In what direction, then, will the development of the future be made?" we asked, and again the answer came back 'High flying, we must get up clear of the belt of disturbed air which results from the irregularities of the earth's surface. From now on you will see a great increase in the average elevation at which aviators will make their flights, for not only will they find in the higher strata more favorable atmospheric conditions, but in case of motor trouble, they will have more time and distance in which to recover control or make a safe glide to earth"

Next we raised the question of suitable starting and stopping places, and suggested that the art of flying was handicapped by the present necessity for broad open spaces for the purpose This brought the reply that since trains, trolley cars, steamboats and sailing yachts are all provided with special points of departure and arrival, it was a little unfair to quote the necessity for such conveniences as an objection to the aeroplane But the problem of alighting, especially during a cross-country flight is not so serious as you might suppose It will be largely solved by the high flying to which I referred just now for, the greater the elevation, the larger the section of country from which the aviator can select a suitable alighting place Suppose," said Wright, "in making a flight, say of 100 miles, I rose to a height of one mile and that while at that elevation motor trouble necessitated an immediate descent. Commencing to glide down the air on a grade of one in seven, I would traverse seven miles of country in a straight line before reaching the ground, that is, supposing that the ground were fairly level But the glide could be made in any direction, and consequently I could choose a landing place on any one of the 150 square miles that would be included in a circle of 14 miles in diameter The chances would be therefore decidedly in my favor of finding some fairly smooth field, free from obstruction, on which I could come down safely"

Of course the question of speed came in for discussion, and the reply to the question whether we shall see any great increase in speed in the near future was characteristic 'Why should we wish to increase the speed? It was only a few years ago that the world believed the construction of a successful flying machine to be impossible and yet there are not many birds that I cannot overtake with that machine" This was presenting the speed question from a new and very sensible standpoint for it must be admitted [illegible] surpassed the average speed of the birds thus early in the game is one of the most sensational achievements of this the latest and most sensational of man's inventions.

THE NEW BRITISH "DREADNOUGHTS" AND "INFLEXIBLES."

Rather complete particulars have lately been made public of the latest British "Dreadnoughts" and "Inflexibles' which are now being built in government and private dockyards Taking the "Neptune" as the latest representative of the Dreadnought' type in the British navy, we find that the length has been increased by 20 foot and the beam by 4 feet, and that the displacement has been increased from 17,900 tons to 20 000 tons The speed, 21 knots, remains the same and no changes of any consequence have been made in the disposition of the armor for the protection of the hull or the barbettes and turrets.

The most important changes—those which serve greatly to increase the power of this ship as compared with the original 'Dreadnought"—relate to the armament In the Dreadnought," it will be remembered ten 12-inch guns were mounted in the following positions Two on the forecastle deck, a pair on each beam amidships on the main deck, with the superstructure between them and four in two turrets on the main deck astern and on the center line of the ship This plan has been changed in the Neptune" by placing the two wing turrets *en echelon* or diagonally, with sufficient distance between them in the fore and aft direction to permit the guns of both turrets to fire on the same broadside Another change is to raise these two turrets and also turret number 4, one deck higher, placing them at the same elevation as the forward turret The aftermost turret will be located, as in the "Dreadnought," on the main deck. By this redistribution the 'Neptune" can fire six guns ahead, eight astern, and ten on each broadside, as against six ahead and astern and eight on each broadside, in the original "Dreadnought." The "Neptune' will carry a new 50-caliber, wire-wound 12 inch gun, and not, as reported, a 13.5-inch gun. For torpedo attack a battery of 4 7 inch guns will be mounted in a lofty central armored redoubt surrounding the smokestacks, which will protect both the guns and the smokestack bases.

The improved Inflexible" known as the "Indefatigable," has 25 feet more length, 3 feet more beam, and 2 000 tons additional displacement than Admiral Seymour's flagship The speed is the same, but the extra 20 feet of length will enable the midship turrets to be placed farther apart in the fore and aft direction than they are in the "Inflexible," with the result that the broadside angle of fire of what might be called the "off turret," that is to say, the turret which is on the side of the ship remote from that on which an engagement is taking place, will be greatly increased

Great Britain evidently is well pleased with her 26 knot battleship cruisers of the 'Inflexible" type, for she is now preparing to lay down on the ways vacated by the 'Indefatigable" another ship of the same type but of far greater dimensions. She is to be 600 feet in length, and equipped with turbine machinery of even greater horse-power than that installed in the "Lusitania" and "Mauretania." As these liners exert over 70,000 horse-power when they are making their maximum speed of 26 knots, it can be understood that to secure the 28 knots required in the new cruiser battleship, the horse-power must run up to 80,000 or more It is probable that the vessel, on her trials, like her predecessors of the 'Inflexible" class, will exceed the requirements by about a couple of knots. The "Inflexible" and her sisters made 28 knots over short distances, and it is likely that the 600-foot ship will be able to carry her battery of eight 12 inch guns for a short spurt across the high seas at a speed of 30 knots an hour, which is higher than the average speed of the torpedo-boat destroyers.

SOME PHOTOCHEMICAL REACTIONS.

A quantity of benzaldehyde, inclosed in a sealed glass tube and exposed to light, is almost entirely converted into a red brown, transparent resin which, when treated with ether leaves a small quantity of a crystalline residue, fusing at 475 deg F and identical with the trimeric modification into which benzaldehyde is converted by the action of iodobenzol.

The resin deposited by the evaporation of the ether from the ethereal solution yields, on distillation, benzoic acid, hydrobenzoin, and unaltered benzaldehyde, and leaves a resinous residue which has the percentage composition, but four times the molecular weight of benzaldehyde, of which it is probably a tetrameric form It may however, be a ketone, of the formula $(C_6H_5)_4$ $(CO)_2$ $(COH)_2$.

Dibenzyliden acetone in alcoholic emulsion exposed to light for a year yields di-isosafrol in addition to the molecular weight of the ketone.

Isosafrol mixed with a trace of iodine and exposed to light for a year yields di isosafrol in addition to a large proportion of resin but safrol is unaffected by light Analogous results are obtained with methyleugenol and isomethyleugenol Propenyl compounds are found to be more affected by light and more readily converted into polymeric forms than members of the allyl group The action of light on mixtures of benzaldehyde with safrol and isosafrol produces resinous substances which, when purified and analyzed, prove to be simple addition products.

THE SPECTRUM OF MARS.

A bulletin has recently been issued by the Lowell Observatory in which the results of Mr Frank W Very's quantitative measurements of the intensification of great B in the spectrum of Mars are given The general result of the investigation is that the great B in Mars is 15 per cent stronger than in the spectrum of the moon at the same altitude, and that B in the spectrum of Mars is relatively more intense by eight times the probable error of the result. Mr Very states that while there is considerable variation, there are no contradictory results. In Mr Very's opinion the measurement proves beyond a doubt, that it is possible to discriminate differences of a few per cent in the intensities of spectral lines, although it would take much wider variations to attract the attention of a casual or even of a careful observer, if deprived of such assistance as can be given by the spectral band comparator In his recent Mount Whitney studies, Prof W W Campbell, of the Lick Observatory, stated that the A band was faint in both the lunar and solar spectra when the bodies were low, fainter when the bodies were higher, and very faint when the bodies were at their highest, but for equal altitudes, the A band in the Martian and lunar spectra were equally intense, plainly signifying that the observed bands were due to water vapor in the earth's atmosphere above the summit of Mount Whitney Here is obviously a conflict which must be settled before we know definitely whether or not the spectrum of Mars does contain water vapor

◆

In the Revue de la Soudure Autogène, Bournonville describes a method of repairing cracked iron pulleys by local heating The crack in the rim is opened by means of an expansion screw acting on the two adjoining spokes, so as to make a gap about 1/16 inch to 1/24 inch in width Welding metal being then melted in the crack by means of the oxy-acetylene flame, the expansion screw is withdrawn quickly, while the metal is still red hot, and the elastic pressure of the rim counteracts the contraction of the joint in cooling. No special care is needed in cooling, and the metal can be tempered without risk of cracking.

AERONAUTICS.

Santos Dumont has been making excellent cross-country flights near Paris of late with a new monoplane, fitted with a 24-horse-power double-opposed-cylinder motor. The machine complete weighs only 242 pounds. The Clement company is building a number of these machines, to sell for about $1,250 each.

The second Aeronautic Show to be held in Paris opened in the Grand Palais on September 25th and lasted three weeks. This exhibition demonstrated how the aeronautic industry has advanced by leaps and bounds within the year. Some thirty different aeroplanes and a score of aeronautic motors were shown, as well as one small dirigible and several plain balloons. A complete description of the show will be given in next week's SCIENTIFIC AMERICAN SUPPLEMENT

Before starting to teach Lieutenants Lahm and Humphries the operation of the recently acquired government biplane, Wilbur Wright tried the machine out on October 9th and had his pupils time him for a distance of a kilometer in a closed circuit. This distance, including the turn, was covered in 48 3/5 seconds, or at a speed of exactly 46 miles an hour Allowing 100 meters extra for the turn, the speed was 50 miles an hour Thus it seems that the new government aeroplane is quite as fast as the Bleriot or Curtiss machines, which made over 47 miles an hour at Rheims.

With the great aviation meet at Rheims as model, almost all the other large cities on the Continent have arranged for a similar event. After Brescia (Italy) and Berlin, Spa, Boulogne, and Dieppe in France, Frankfort in Germany, and Blackpool in England have put up large cash prizes to secure Latham, Bleriot, Farman, and some of the less well known but fully as daring aviators. The Frankfort authorities even went so far as to pay the traveling and hotel expenses of the "bird men." A big meet was held at the new Juvisy aerodrome near Paris from the 7th to the 21st of this month, no less than 37 machines being entered of which 13 were Voisin biplanes On October 10th thousands of people flocked to Juvisy The train service was inadequate and there was such a demonstration by the crowd that the troops had to be called out.

On October 13th a course of lectures upon aviation to be given by Wilbur R. Kimball was inaugurated at the rooms of the Young Men's Christian Association, 318 West 47th Street, New York city Besides Mr Kimball's lecture, which was illustrated with a number of models, Mr Hudson Maxim, the inventor of maximite and an authority upon explosives spoke upon the dropping of explosives from aeroplanes. He thought the public should be rid of the fallacy that much harm can be done in this way The aeroplane, he believes, will be used for scouting and raiding but not as an instrument of destruction in itself Mr. Winthrop E Scarritt, an ex-president of the Automobile Club of America, gave an interesting talk on the future of aeronautics.

In connection with the Centennial Celebration at St. Louis, Glenn Curtiss made a number of short but good exhibition flights There was also a balloon race on the 11th instant, in which 10 balloons competed. The "St. Louis III.," piloted by Louis von Phul, won, covering 545 miles in 41½ hours duration, and landing at Lawrence, Minn. The "Indiana," with H H. McGill pilot and J M. Schauer aide, landed near Albany, Minn., 500 miles distant. Mr McGill was taken violently ill, and his aide was finally obliged to bring the balloon to earth to get medical assistance. The "Centennial," H R. Honeywell pilot, made a flight of 480 miles and landed at Silas, Ala. The "Cleveland," J Wade, Jr, pilot and A. H. Morgan aide, covered 456 miles and landed near Alexander City, Ala. Baldwin, Knabenshue, and Beachy also made flights at the celebration in their dirigibles. Messrs. Post and Harmon, in the "New York," won the endurance race in 48 hours 26 minutes.

The third international balloon race for the Bennett trophy started from Schlieren (near Zurich), Switzerland, on Sunday, October 3rd. There were 17 starters representing 9 nations and divided as follows America 1, Austria 1, Belgium 2, England 1, France 3, Germany 3, Italy 2, Spain 1, Switzerland 3. For the second time in four years the cup was won by an American, Mr. E. W. Mix, of Columbus, Ohio—our sole representative—having the good fortune to travel over 648 miles in 35 hours, and, after passing through a drenching rain and having some exciting experiences in the Bavarian Alps, to finally land in the trees in the forest of Gutova, some miles north of Warsaw in Russian Poland. Mr. Mix and his aide were obliged to throw out their life preservers and provisions in order to keep afloat so long. After doing this at Breslau early Monday afternoon, they rose to a height of 9,000 feet, from which elevation they gradually fell until the balloon landed at 8 A. M. October 5th. Second place went to Alfred Leblanc with a record of [illegible] miles.

ELECTRICITY.

The New York Public Service Commission reports that 3,337 persons were injured last August on the surface traction lines of New York city This is 12 less than the record for August, 1908. The serious injuries for this August were 304, or 33 less than for the corresponding month of last year

The Canadian Pacific Railroad has found the telephone so serviceable for train dispatching that the present system of about 500 miles of telephone lines will be extended to 1,000 miles within a year The company states that about fifty per cent more traffic can be handled now than was possible under the old telegraph system of dispatching

Every once in a while we hear of wireless telegraphic communication over an enormous range Recently the army transport "Buford," while nearing Honolulu, succeeded in exchanging messages with the Pacific coast. The distance covered was 3,500 miles. This does not mean that there has been a wonderful advance in wireless telegraphy, but merely that atmospheric conditions were unusually favorable.

The electrification of the street railway line from Woolwich Arsenal to the London County Council free ferry has been brought to a halt owing to possible disturbance of the delicate instruments at Greenwich Observatory The Astronomer Royal has the power to stop any undertaking within three miles of the observatory that is liable to affect the instruments, and the railroad company must obtain his consent before proceeding with the electrification

Manufacturers of electrical apparatus have recently awakened to the fact that there is quite a demand for a transformer which will permit of operating electric bells, buzzers, toys, etc., with current taken from line circuits in place of storage or primary batteries. Small direct-current battery apparatus may ordinarily be operated on an alternating current without any change in the windings or connections, provided the voltage is sufficiently reduced A transformer of this type has recently been put on the market, which will reduce from 110 volts to from 8 to 26 volts.

A very ingenious method of overcoming the friction of intermeshing gears has recently been devised The gear teeth are electromagnetically held in engagement, without actually contacting The teeth of the driving gear are magnetized by means of suitable coils, while the teeth of the driven gear serve in pairs as armatures for the magnetized teeth Of course such an arrangement would hardly be suitable for slow, heavy work, because the cost of current would be greater than that of lubricating oil and the loss due to friction but for light, high-speed work the electromagnetic engagement would undoubtedly prove very advantageous

Portable telephone instruments are being made by the Western Electric Company for use on interurban electric railways The telephone instruments are carried on the cars, and stations are located at various points along the line. The conductor or motorman can connect the instruments to the station by merely inserting a pair of line plugs, and thus can get into direct communication at once with the dispatcher In case of delay on the road, or an accident these instruments are invaluable, as they enable the dispatcher to learn the particulars at first hand, and make arrangements to relieve the situation

An apparatus for sterilizing water has recently been put on the market in France in which ozone is used to destroy the bacteria. The ozone is generated by means of electric discharges, and the gas is introduced into the water by means of an aspirator The ozone is led into a mixing tube screwed to the water faucet, and the water is forced by a small pump through several compartments, so that it is divided into a number of fine jets. In this way an intimate mixture of the gas and water is obtained The device is so arranged that the ozone is generated only when the faucet is opened

A large electric freight locomotive is being built for the New York, New Haven & Hartford Railroad, with which it will be possible to test thoroughly the advantages of handling freight trains electrically The locomotive will also be used for hauling heavy passenger trains. Following the present tendency, the motors are placed above the axles, thus raising the center of gravity and reducing the shocks and strains to which the roadbed and track are subjected by locomotives in which the motors are mounted on the axles. The locomotive is mounted on two trucks, one of which is pivoted on a center pin, while the other has a fore-and-aft movement as well as a pivotal movement, permitting it to negotiate curves. Four 350 horse-power single-phase motors are used, which may be operated either with 11,000-volt alternating current or 600-volt direct current. A flexible connection between the power and the wheels is accomplished by gearing the motor to a quill on the axle which is provided with driving arms that project between the spokes of the wheels. These arms are connected with coil springs, which serve to absorb shocks and strains of transmission and equalize the torque on the gears.

SCIENCE.

The Cook-Peary controversy will probably be settled by a commission of inquiry appointed by Dr Ira Remsen. The commission will examine and report on the Arctic records, observations, and data collected by both explorers.

Boomerangs are now made of celluloid and hard rubber Celluloid is better than cardboard because it is waterproof, light, very hard to break, and can be worked into the peculiar curve and twist so necessary to give the boomerang its peculiar properties.

The owners of a St. Abbs fishing boat have made the important discovery that a net dyed as nearly as possible the hue of the sea instead of the traditional brown yields much larger results in the matter of fish caught. The discovery was says the Western Morning News put to the test a short time ago when, out of a fleet of sixty-five boats the boat with its nets dyed blue made far and away the largest catch. The dye used is bluestone. The discovery has aroused much interest among the fishermen.

Peat, as it comes from the bog, contains from 85 to 95 per cent of water According to Dr Ekenberg it appears that the peat contains a hydrocellulose which is of the nature of a jelly If the peat is subjected to pressure the hydrocellulose passes through very much as soft soap might, and without separating the water from the peat If, however the peat is heated to about 320 deg F this jelly is immediately destroyed, and most of the water can be separated by a pressure of about 240 pounds per square inch

The steamer 'Conqueror' at Leith has been chartered by Dr W S Bruce Edinburgh the leader of the recent Scottish National Antarctic Expedition for the purpose of undertaking another expedition to the polar regions The expedition it is expected will be ready to sail in a little more than a fortnight. The present intention is that the expedition will be away for two or three months Important observations in the neighborhood of Spitzbergen are premeditated Dr Bruce being a recognized authority on that region

A process has recently been patented by two Italian gentlemen for rendering calcium cyanamide inoffensive At present this product has several serious drawbacks owing principally to its causticity, and the ammonia and hydrocyanic ethers which it gives off. The process in question proposes to add sulphuric acid diluted with its weight in water to the cyanamide, after introducing the cyanamide in small quantities to the liquid, the whole should remain slightly acid After an intimate mixture the product is dried at 40 to 50 deg C, and then pulverized.

The following experiment, writes Mr C S Jackson, in Nature, is easily tried and throws some light on a certain type of illusions A small cogwheel from an old American clock is the only apparatus required Holding the axle in the finger and thumb of the right hand, give it a twirling motion say counterclockwise Let the teeth of the wheel click gently against a small card, or the finger nail of the left hand On looking at the wheel the spokes appear to revolve counter-clockwise (as they do) and the teeth to revolve in the reverse direction

Radium appears to have a marked action on the development of the eggs of the *Philine aperta* M Jan Tur, of Paris, made a series of over forty experiments with a very strong radio-active preparation about 9 milligrammes of radium bromide acting through a thin glass plate upon the eggs in different stages. In the first stages of development the eggs do not seem to suffer from the effect of the radium but after a certain period it is found that the organs will no longer be formed A longer exposure causes the larvæ to shrink up and they become only one-fifth of their normal size. After 6 to 9 days there remains nothing but a shapeless mass of cells and the mass is observed to have a rapid rotary movement inside the shell of the egg The larvæ are found to die in 9 or 10 days after the laying of the eggs without being able to leave the shell

The occurrence of ores of tungsten in Canada is the subject of a report by Dr T L. Walker recently issued by the Canadian Department of Mines After pointing out that the metal is used not only in the manufacture of metallic filament electric lamps but also in the production of tungsten steel and of the tungstates which are employed as a mordant in dyeing in giving weight to silk goods, and in rendering cotton goods fireproof he goes on to give particulars of the chief tungsten ores, their geological occurrence and the methods used in treating them, as well as some statistics of the world's production of them which has been advancing rapidly of late years He then gives a detailed account of the occurrence of such ores in Canada, and finally remarks that, though no tungsten production has yet been credited to the Dominion and that she has no well-developed and established tungsten ore mines, still there are many districts where such ores occur.

THE FIRST GERMAN MONOPLANE TO MAKE SUCCESSFUL FLIGHTS.

Our illustrations show the monoplane of Herr Grade, who is the first German to make successful flights in a heavier-than-air machine. This monoplane resembles that of Santos-Dumont in its general make-up, the aviator being placed below the plane, and the motor—a 4-cylinder air-cooled engine of the V type—being located at the front edge, and carrying a propeller on its crank-shaft The wings of the monoplane are set at a slight dihedral angle, and are provided with a flexible edge at the rear A tail with vertical and horizontal surfaces is mounted upon a bamboo pole extending out behind.

While making an attempt to win the Lanz prize of $10 000 at the Mars aerodrome near Berlin, Herr Grade experienced a bad fall, fortunately without injury The flight required was one of 2½ kilometers (1.55-mile) in the shape of a figure eight. The aviator made a splendid start, but in the middle of his flight, when at a height of nearly 100 feet, the propeller broke, and the machine came forcibly to the ground Fortunately, the shock of striking the ground was lessened by the alighting of the monoplane in some low pine trees. The machine was badly damaged but Herr Grade expected to repair it in a few days.

This is the first German aeroplane to make satisfactory short flights.

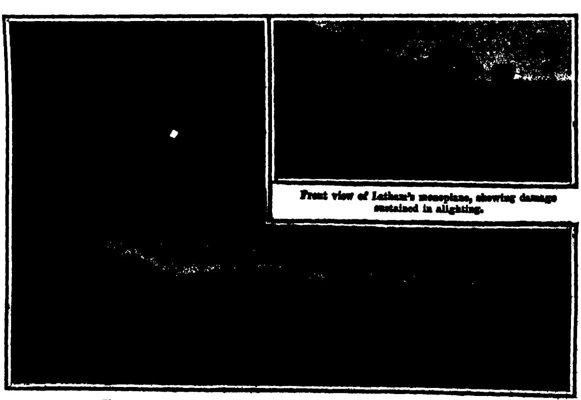
THE GRADE MONOPLANE IN FLIGHT

◆

THE AVIATION MEET AT BERLIN AND LATHAM'S FLIGHT ACROSS THE CITY

The aviation meeting which was held recently at Berlin was specially noteworthy for the great feat of Hubert Latham in flying across the city of Berlin from the Tempelhofer field to the aerodrome at Johannisthal. This flight was made on September 27th, the second day of the meeting, and it has already been mentioned in these columns. Our photograph shows the machine as it flew across the sheds which were erected for the aeroplanes at Johannisthal. The great height at which Latham flew is indicated by the small size of the monoplane, which looks like a huge bird of prey winging its way in the upper air Latham made the flight of 6¼ miles across the city in less than 10 minutes. He first made two circuits of the Tempelhofer field and then started straight off across the city at a height of about 300 feet As soon as word was received by the waiting spectators at Johannisthal that Latham had started they all strained their eyes in an effort to see the machine in the distance. Soon it appeared a mere speck in the sky It came rapidly nearer, and finally passed overhead as shown in our illustration Before coming to earth, Latham completed two circuits of the aerodrome, a distance of about 12½ miles. Upon alighting, he received a decided ovation The total length of his flight was about 24 minutes.

The opening day of the meeting Sunday September 26th, was not very auspicious Baron De Caters made several circuits of the 2½-kilometer (1 55 mile) course, and Bleriot did likewise. Neither aviator kept aloft long enough, however, to qualify for the speed prize. Leblanc started on his Bleriot monoplane, but only succeeded in making a half round of the course



Front view of Latham's monoplane, showing damage sustained in alighting.

The arrival of Hubert Latham at Johannisthal after his flight across Berlin.

In this instance for the first time an aviator arrived at an aviation meeting on his machine, after taking a direct air line.

THE AVIATION MEET AT BERLIN AND LATHAM'S FLIGHT ACROSS THE CITY

On September 27th very little was accomplished, but the following day several excellent attempts were made to win prizes, the best of these being that of Rougier who flew 44 75 kilometers (27 78 miles) in 52 minutes Latham and Farman both attempted to win the speed prize. The former covered the required distance of 20 kilometers (12 42 miles) in 18 minutes 4 3/5 seconds, and the latter in 20 minutes 9 2/5 seconds. M Bleriot did not quite succeed in completing the 20 kilometers. Rougier in his long flight, attempted to win the height prize presented by Count Zeppelin, but he only reached a height of 100 meters (328 feet). Edwards, who was operating a Voisin biplane, had a bad tumble after completing three circuits of the course. He fortunately escaped with only a few slight cuts. Baron De Caters damaged his biplane in making a sudden landing

On September 29th, Rougier made 31 rounds of the course, and covered an official distance of 77½ kilometers (48.12 miles) in 1 hour and 27 minutes, a speed of 28.73 miles an hour Latham covered 67½ kilometers (41.91 miles) in 1 hour and 14 minutes. His average of 41 22 miles an hour in the 20-kilometer speed test caused him to be declared the winner of the speed prize of $2,000 On October 1st Rougier won the distance prize of $10,000 for 2-hour 41 minute 50-second flight, in which he covered 80¾ miles at an average speed of 30 miles an hour

M Bleriot's monoplane was attached by the management when the champion aviator attempted to leave with it for Cologne. He had been paid $5,000 to fly at Berlin on five days, and because he refused to stay, his machine was retained. M. Leblanc also stopped when Bleriot quit. On the whole, this meeting was fairly successful, especially in view of the fact that it was run during the time of the aeronautic show at Paris, which opened on September 25th. Latham struck the ground forcibly in one of his landings, breaking a wheel and damaging his propeller as shown in one of our photographs.

◆

Holland compound is a solution of 5 parts of soda water glass and 1 part of carbonate of soda, or a powder mixture consisting of 3 parts of calcined soda and 1 part of dry potash water glass. Ten parts of this mixture is said to be sufficient to render 100,000 parts of hard water soft.

Suicide of Scorpions

The venoms of serpents, fishes, scorpions, centipedes, spiders, bees, etc., as well as the blood of the eel, owe their virulence to the presence of toxins similar to those which are secreted by bacteria. In both cases the toxins are specific products of the activity of living cells. They are very poisonous, non-crystallizable colloids, of unknown chemical constitution. The venom toxins are very sensitive to the action of heat and light, are easily destroyed by digestive ferments, and consequently are innocuous when swallowed. There is a great variety of these toxins. Such a poison alone contains half a dozen distinct toxins, each of which exerts a specific action on the nervous system, the red or the white blood corpuscles, etc.

It is possible to produce in any animal an artificial condition of immunity to the effects of any animal venom This is accomplished by the repeated injection of the venom in doses, each of which is too small to cause death. After a larger or smaller number of injections the animal acquires the power to resist the action of many times the quantity of venom that would suffice to cause death, if it were injected into the veins of a non immunised animal. The blood of the immunised animal now contains a new substance, an antitoxin which has the property of neutralising the toxin of the venom, and this blood (or rather its watery part, or serum) may be employed to combat the toxic action of the venom in a non-immunised animal.

The ichneumon, the hedgehog, and some other animals which devour venomous serpents, exhibit an extraordinary resistance to the effect of their bites. This natural immunity is explained by the presence of antitoxins in the blood of these animals. Serpents are also little affected by their own venom In general, it is almost impossible to kill a venomous animal by inoculating it with the venom of its own species, of which it can support very large doses with impunity

These facts demonstrate the absurdity of the stories of rattlesnakes and scorpions committing suicide by means of their own venom. It is asserted that a scorpion or a rattlesnake imprisoned in a circle of red-hot coals will sting or bite itself to death. This is a physiological impossibility —Cosmos.

Common iron scrap has now so low a commercial value that it is hardly worth the trouble of selling, unless it has accumulated in large quantities. But there is a difference in scrap, as the following story proves. A French ship recently sailed from Oakland, Cal for Genoa, with a cargo of iron scrap collected from the ruins of San Francisco, after the earthquake and conflagration of 1906. The scrap is consigned to the Italian government and is to be used in the construction of a warship of the "Dreadnought" type. It appears that a small lot of similar material, which was brought to Genoa two years ago and mixed with steel, produced armor plates of unusual strength. In consequence of this result, which was due to the intense heating which the scrap had experienced in the conflagration, the Italian naval engineers advised the government to purchase all the scrap iron from the San Francisco fire that could be obtained

The United States Treasury Department will soon take up the subject of providing sanitary paper money. Not the least of the reforms proposed is the proposition to wash national bank notes. It is said that the idea of washing bank notes is by no means infeasible, for it is possible by means of a chemical solution or bath to clean the notes without injuring the [illegible]

A SIMPLIFIED METHOD OF TEACHING EXPERIMENTAL PHYSICS.

BY JACQUES BOYER.

Until recently, experimental physics has been taught by rather superannuated methods in the *lycées* and colleges of France The teachers lacked simple apparatus suitable for the initiation of their pupils into the mysteries of acoustics optics, electricity and magnetism although some of the schools possessed magnificent instruments copies of those of half a century ago which in the language of M Chassagny the inventor of the apparatus described below were a joy to their makers but of little use to their possessors There were costly Heros fountains and Morins machines which were used only once a year The pumps and hydraulic presses were equally expensive and they gave the pupils a totally false conception of the pumps and hydraulic presses employed for practical purposes Babinets improved pneumatic apparatus is remarkable chiefly for its great display of polished copper The Gay Lussac eudiometers Ramsden electric machines condensers of Aepinus Watts s machines and many others have now only historical interest For several years French teachers of physics have been trying to modernize their cabinets of apparatus and to modify their instruments in order to simplify experimental observations Prominent among these progressive teachers is M Chassagny inspector of the Academy of Paris who has invented a number of efficient instruments of neat and substantial though inexpensive construction with each of which various instructive experiments can be performed

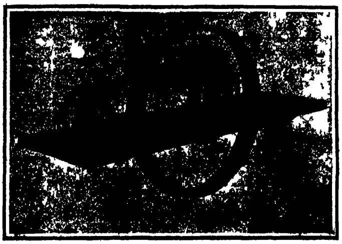

Fig 1 —The mechanical recorder.

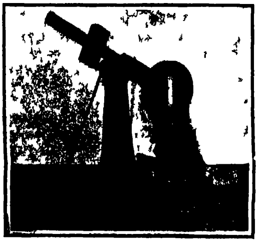

Fig 6.—Chassagny's apparatus for electromagnetic induction

Fig 2.—Apparatus for combining vibrations in the same plane

The complicated machines of Atwood and Morin for the study of the laws of falling bodies are replaced by the mechanical recorder (Fig 1) which is useful also in explaining the laws of the compound pendulum and the graphical method of recording movements in general. A bicycle wheel is mounted with its axle horizontal in a flat wooden frame The rim of the wheel carries a wide band of sheet brass forming a sort of drum which can be covered with a band of smoked paper and one end of the axle bears a small grooved driving pulley The center of gravity can be brought accurately to the axis of rotation by means of sliding weights attached to two of the spokes At one side of the drum a short pendulum formed of a heavy cast iron cylinder is mounted on an axis perpendicular to that of the drum on the blackened surface of which a record is traced by a flexible needle attached to the pendulum The drum and the pendulum can be stopped together or separately by means of an adjustable lever and the driver is also provided with an emergency brake

With this apparatus some fifteen experiments can be performed illustrating the static equilibrium of moments inertia the action of constant forces the law of velocities proportionality of force to acceleration resistance of the air friction isochronism of small oscillations the graphic method of registering movements etc

In demonstrating the principle of inertia the needle is brought into contact with the band of smoked paper carried by the drum and the drum is turned The pendulum being in the position of equilibrium the needle traces a line which when the paper is removed and laid flat will be straight and will constitute a base line This line having been traced the pendulum is drawn to one side a rotary impulse is given to the drum with the hand the pendulum is released by moving the lever which holds it and the needle traces an undulating line The distances between consecutive intersections of this line with the base line represent equal intervals of time corresponding to equal vibrations of the isochronous pendulum and as these distances are also found to be sensibly equal in length the experiment proves that the drum set in motion by a momentary impulse continues to rotate with practically uniform velocity (the effect of friction being negligible)

In studying the action of a constant force the base line is traced as before A cord is then wound round the drum and a weight of about one-quarter pound is attached to its free end as shown in Fig 1 The zero point is marked by allowing the pendulum with its needle to swing across the base line while the drum is held at rest The pendulum is then drawn aside and by a proper adjustment and manipulation of the lever the pendulum and the drum are released simul

A SIMPLIFIED METHOD OF TEACHING EXPERIMENTAL PHYSICS.

A New Process for Developing Photographs in Daylight.

If an ordinary dry plate, after it has been exposed in the camera, is placed in a bath of potassium iodide, the silver bromide is converted into the non-sensitive iodide and the latter can then be developed in daylight with a suitable developer It is recommended to carry out the process as follows

The plate is laid for two minutes in an actinal solution (i e four per cent potassium iodide) This can be done in a suitable cloth bag. After this the development may be carried out in subdued daylight using equal parts of the solutions A and B

A.

Water	600 grammes.
Anhydrous sodium sulphite	20 grammes
Metol	1 gramme.
Hydroquinone	8 grammes.
Potassium bromide	40 grammes.

B A three per cent caustic potash solution.

The plate should of course be rinsed before developing The latter operation takes about five minutes. The fixing is carried out as usual except that it takes a little longer The exposure should be ample The potassium iodide solution may be used over and over, but the developer should be mixed fresh for every plate —Chemiker Zeitung

◆

Limitation of the Speed of Automobiles.

In England a recent municipal police ordinance requires high power automobiles to carry apparatus which will give warning when the city speed limit is exceeded or will automatically diminish the speed in such cases. An apparatus of the first class which is much used, consists of an air-compressing cylinder prolonged at the bottom by a smaller cylinder containing a piston which has two peripheral vents and is forced forward by a spring.

The piston of the air-compressing cylinder is connected with the driving mechanism, and its velocity is proportional to the speed of the vehicle So long as this speed is below the prescribed limit, the pressure of the air which continually escapes through one of the vents of the small piston remains too low to move this piston and compress the spring. When the legal speed limit is exceeded however, the pressure rises, and the small piston is forced back until the second vent comes opposite a whistling vent in the wall of the small cylinder, so that the whistle is sounded by the escaping air

An apparatus of the second class comprises an oil pump, the pipe of which is provided with a three-way cock This cock is controlled by a centrifugal regulator, and its third channel communicates with a cylinder containing a piston which controls the accelerator, the brake, and the transmission When the speed exceeds the normal limit, this third channel is opened by the action of the centrifugal regulator, and the oil is forced into the cylinder where, by its pressure on the piston which operates the brake, etc, it reduces the speed of the vehicle to the normal limit. This limit is indicated on a dial, and it can be varied by adjusting the spring of the centrifugal regulator by means of a key

Himly gunpowder contains 45 per cent chlorate of potash, 35 per cent of saltpeter, and 20 per cent of coal tar In making it up the tar is dissolved in benzine, the solution mixed with the salts and the benzine then evaporated.

SATURN AND HIS RINGS.

BY PROF. FREDERICK R. HONEY, TRINITY COLLEGE.

The study of Saturn and his rings is one of the most fascinating in astronomy. The enormous bulk of the planet (second only to Jupiter in diameter); its low density (less than that of any other planet), the great difference between the polar and equatorial diameter, and the rapidity of its axial rotation, alone make Saturn an object of peculiar interest. But the conspicuous features of the Saturnian system, viz., the vast rings and the brilliant retinue of ten satellites, which distinguish the planet from the other members of the solar system, constitute the problems of chief interest in the study mentioned.

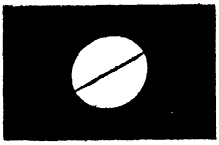

Fig 1 —SATURN'S RINGS IN 1907

Among the many advances in astronomical discovery is included a more accurate knowledge of Saturn's rings, the plane of which coincides with that of the planet's equator It has been clearly proved that the theory of a rigid ring is untenable, and this view has long since yielded to the more scientific conclusion which maintains that the rings are in a mobile state, and that they are probably composed of swarms of meteors or satellites too small to be distinguished in the telescope. These bodies, obedient to the laws which govern the motions of satellites around their primary, would arrange themselves in the order as it now exists. The complexity of the problem is apparent. Since the thickness of the rings is not more than a hundred miles, and the diameter of the outer ring about one hundred and seventy thousand miles, the dimensions of these bodies must be very small, and their number extending over such a vast area well nigh incalculable. The installation at the present time of larger reflectors in our observatories augurs well for the value of observational work, and it is to be expected that in the future a more accurate knowledge of the constitution of the rings of Saturn will be obtained.

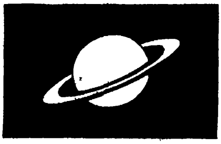

Fig 2 —SATURN'S RINGS IN 1909.

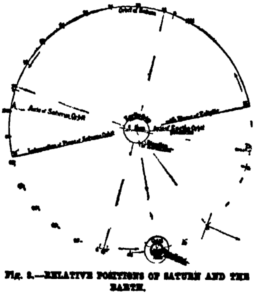

Fig. 3.—RELATIVE POSITIONS OF SATURN AND THE EARTH.

Saturn is now in that quarter of his orbit which includes perihelion. At an opposition which is near perihelion the planet approaches nearly one hundred million miles nearer the earth than at an aphelion opposition. As a consequence the apparent diameter of the planet and of the rings will increase at each opposition until perihelion is reached.

The plane of Saturn's orbit is inclined at an angle of nearly 2½ degrees to the plane of the ecliptic. In the diagram the full line represents that part of the orbit which is above the ecliptic; the dotted line the part below. The intersection of the plane of the orbit with that of the ecliptic is N N', and these points are respectively the ascending and descending nodes. A P is the axis of the orbit whose center c is nearly fifty million miles from the sun. The revolution of the planet at a mean distance of 886 million miles from the sun is accomplished in nearly 29½ years; oppositions occurring at average intervals of 378 days. The positions of Saturn at successive oppositions are shown from 1891 to 1911. The plane of the rings is inclined at an angle of 28 degrees to that of the ecliptic, and the plane traverses the earth's orbit twice during each revolution in opposite directions in a little less than a year (= 360 days) When it passes through the sun it is pierced by the planet's orbit at a and d, the positions of Saturn at opposite points in the orbit, which are reached at intervals of about fifteen years. When the planet is at either of these positions an edge view of the rings is presented to the sun. The extreme points of contact of the plane of the rings with the orbit are b and e, and when Saturn is at either of these positions the rings are seen to the best advantage, i. e., they open to their greatest apparent width. The minor axis of the ellipse representing each ring is nearly one-half the length of the major axis.

At the date of the opposition of 1899 the planet was near b, and a satisfactory view of the northern hemisphere of Saturn and of the upper surfaces of the rings was obtained At the opposition near e the southern hemisphere and the under or southern surfaces of the rings will be visible. Also the planet will be nearer the earth, and the apparent dimensions increased about one-eighth. Saturn will be in the northern heavens and therefore seen to good advantage in high latitudes The plane of the rings traversed the earth's orbit in 1891 2 Fifteen years later, in 1907, this plane again crossed the earth's orbit, and an edge view was obtained. Fig. 1 shows Saturn and his rings in this position, making apparent the difference between the polar and equatorial diameters The thickness of the rings is estimated between fifty and one hundred miles. But this measurement is so small in comparison with the diameter of the ring that it is impossible to represent it in correct proportion by the scale of the figure The fine white line may therefore be accepted as a representation of the rings for a short period of time just before and after the edge view was presented, when they entirely disappeared, and the planet alone remained visible. The positions of Saturn and the earth are shown at the date of opposition in 1909 It is scarcely necessary to say that while the planets are correctly proportioned in the plot, their dimensions are enormously exaggerated in order to compare their magnitudes. If they were drawn to the scale of the orbits they would shrink to mere points. Saturn's axis moves parallel to itself. To an observer on Saturn (if life were possible on the planet) the heavens would appear to move in the same general direction as they appear to us, but around another pole, and in less than half the time, as Saturn's rotation on his axis is accomplished in about ten hours and a quarter

Two years have passed since the edge view was presented to the earth. The rings are gradually widening, and their under surface becoming visible. Fig. 2 shows saturn and his rings as seen in a telescope at the date of opposition this year As the telescope gives an inverted image, in order to obtain a correct view Fig. 2 should be inverted. The larger area of the planet in the drawing represents the southern hemisphere which is turned toward the earth. The figure shows the division between the outer and inner rings, and between the "crape" ring and the planet. At each successive opposition the rings will widen and the markings on their southern surfaces will be more easily distinguished.

The present time offers an excellent opportunity for a telescopic study of Saturn and Mars. Both planets are evening stars, and both are near opposition. They are slowly approaching each other and will be in conjunction on December 31st.

◆

Various salts added in small quantities to the water used in mixing Portland cement appreciably accelerate or retard the setting of the mixture. The setting is retarded by water containing 4 per cent or more of sodium chloride, and by weak solutions of calcium chloride, but the latter salt in concentration higher than 9 per cent acts as an accelerator. Aluminium chloride accelerates, while iron chloride, most soluble sulphates, and even plaster of Paris retard setting. Aluminium sulphate is an accelerator, and in the compound alums its effect preponderates over that of the retarding alkaline sulphates and produces a slight acceleration. The alkaline carbonates accelerate in weak solutions, but soda acts as a retarder when its concentration exceeds 10 per cent. [illegible] phosphates, chromates, and chromic acid [illegible] centration retard the setting.

Correspondence.

AN OLD PADDLE-WHEEL BOAT.

To the Editor of the SCIENTIFIC AMERICAN

Among the odd boats in your recent issues, I failed to note a duplicate of one I saw in Canadian waters. It was a small excursion boat, sidewheeler, propelled by power furnished by a team of horses working on a treadmill. The speed was not great, but the boat surely moved, and furnished amusement for a goodly party which it happened to have the day I saw it. A band was playing and people shouting as we sped by on a steamer. J DOUX.

THE HEIGHT OF MOUNT RAINIER.

To the Editor of the SCIENTIFIC AMERICAN

Reading to-day in a recent issue of the SCIENTIFIC AMERICAN, I saw this statement in reference to Mount Whitney "This peak is the highest in the United States." Height given, 14,501 feet.

I was with Prof. McClure in 1897 when he ascended Mount Rainier, and helped him to carry instruments for use in determining the height Although he was killed in the descent, his notes were complete, and the subsequent calculations made from them by his friends gave the height as 14,528 feet above sea level. I believe these figures have been accepted as the true height. HARVEY F. MITCHELL.

WHY NOT A MONUMENT TO FITCH?

To the Editor of the SCIENTIFIC AMERICAN

It gave all members of my family great pleasure to read the SCIENTIFIC AMERICAN editorial of October 9th. It strikes the keynote of the situation in regard to our unequal distribution of acknowledgment to steamboat inventors. My father (James Arthur) pronounces it the best column that has appeared to date.

We of course all realise that it is impossible to do honor to all the early inventors, but we should at least do justice to the United States of America by placing its steamboat successes in the right century We have just been celebrating the fact that the United States had a steamboat in the nineteenth century while as a matter of fact we had several successful ones in the eighteenth century, and the one referred to in your editorial attained a speed which was not exceeded until the following century was several years old.

We all hope that your timely remarks will bear fruit and that a bronze tablet will be placed near Collect Pond, and that the grave of John Fitch may at least be properly marked. DANIEL ARTHUR.

"INFLEXIBLE" AND "CONNECTICUT" COMPARED.

To the Editor of the SCIENTIFIC AMERICAN

Pardon me for the presumption of criticising anything in your very valuable paper, but an article in the issue of October 9th, dealing with the visiting warships anchored in the Hudson River, I think is misleading in one particular In comparing the broadside fire of the three battleships representing France, England, and the United States, the statement is made that the "Inflexible" has eight 12-inch guns which can be fired on one broadside. But, if I am not mistaken, the "Inflexible," like all her sister "Dreadnoughts" of the English navy, is unable to fire all her 12-inch guns on both broadsides, on account of the position of the two wing turrets. If this is true, then the "Inflexible's" superiority would be mainly in her great speed I believe that the "Connecticut," with her rapid-fire 8-inch and 7-inch guns, coupled with her four 12-inch guns, would more than hold her own with an "Inflexible." Although the 8-inch and 7-inch guns, theoretically, will not penetrate the "Inflexible's" amidship armor belt, still the rain of shells from these lighter guns would play havoc with every part of the vessel above the low 7-inch armor belt of the English cruiser This would not affect the crews in the 12-inch turrets, but when the ship is riddled fore and aft, with all the [illegible] and quickly overcome the "Connecticut," by the mere concentration of her 12-inch guns. Now, I think it would be extremely unhealthy for the "Inflexible" at this range, as the terrible broadside of the "Connecticut's four 12-inch, four 8-inch, and six 7 inch guns would completely overwhelm the six 12-inch of the former Even admitting that the 7 inch guns of the "Connecticut" are protected with comparatively light armor, still the tremendous rate of fire of that battery in addition to the four 8-inch and four 12-inch, would so blind the gunners on the enemy that they would be unable to properly handle their guns. Even up to 9,000 yards, the 8-inch and 7 inch guns would be very effective in carrying away the upper works of an enemy, thus destroying his ability to handle his ship. So I would like to see our "Connecticut" placed in a more favorable light in a comparison with the "Inflexible." EMERSON B MANLEY

U S S "Kansas." Machinist's Mate

[We mentioned in the article referred to that the secondary battery of the "Connecticut" would riddle the unprotected parts of the "Inflexible." The mid ship pairs of 12-inch guns on this ship are placed diagonally, and therefore all four guns can be fired on either broadside, through a limited angle.—ED]

RESULT OF A LIGHTNING STROKE.

To the Editor of the SCIENTIFIC AMERICAN

The accompanying photograph was taken recently at Velva, N D. Three young men were putting up hay, when a thunderstorm came up, and all three were knocked down, the lightning killing a team of horses, and rendering the two men who were holding them unconscious for some hours. The third man saw the others fall, and then lost consciousness himself His team, standing a couple of rods away from the other was knocked down, and a hole was torn in his cheek whether from the fall or from the lightning it might be impossible to say He came to, mounted a horse, after pulling one of his companions from under one of the dead animals, and rode for help Securing that, he returned, and then fainted, partly from loss of blood, and remained unconscious several hours. The other two men regained consciousness that night, and all three were practically over the effects of the stroke within a week after the occurrence The photo shows a new pair of shoes worn by one of the men, and a new, heavy pair of overalls, just as they were taken from him after the accident HUGH J HUGHES.

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN

If you and your readers are not tired of this question, may I suggest another solution than that Mr Solon De Leon gives? I may perhaps point out that, originally, I simply stated the problem, did not say it vexed me, and made no false sociologic assumption

Let X represent the first generation, and so assume $X = 2$ Assume continuity of descent, and let X^y represent some later generation We need not trouble about what value we give to y, all we want is that the number of individuals of the generation is represented by X^y. We get, say, 20,000 000 of individuals descended from 2 original individuals, and see at once that there is some consanguineous relationship between all the individuals of the X^y generation. So, if we assume all of us now existing are descended from some original man and woman, it is clear we are all of us consanguineously related

Now consider any one individual existing at the present time Then his parents are consanguineously related, but in most cases the blood relationship is so remote that he will treat the relationship as *non-existent* We have, in the simple form of the problem I use a series, X X^1, X^4 X^y, where each individual of the X^y generation relates back in consanguinity to the original generation X but there being so many intermediate generations, his *collateral* consanguinity to any other individual of his generation is so remote that to him it is non-existent For an example of this we have the fact that man as an organism is related to the monkey as an organism through some arboreal ancestors But the *collateral* consanguinity is so remote, that we treat it as non-existent. THE HIGHEST HUMAN ASCENT

To the Editor of the SCIENTIFIC AMERICAN

On page 239 of your issue of October 2nd 1909, you state "The record of altitude in aeronautics has been attained by Sig Piacenza and Lieut Mina in an ascension made from Milan on August 10th 1909 Their great spherical balloon reached an elevation of 38,700 feet, or more than seven miles." This statement, based probably on the press reports, is incorrect, as proved by a letter from the aeronauts themselves, Messrs Mina and Piacenza, published in the French journal L'Aérophile of September 1st, from which it appears that the maximum height was only about 9,200 meters or 30 180 feet. Since their cotton balloon held only 80 500 cubic feet and contained illuminating gas, this was a remarkable performance, and though there is some doubt as to the barometric observations, it probably exceeds both the French and Italian records. The world's record is however still held by Messrs. Berson and Süring who ascended from Charlottenburg, near Berlin, on July 31st, 1901, in a balloon of nearly 300 000 cubic feet capacity partially filled with hydrogen gas, to the height of 34 450 feet.

AERIAL WARFARE IN 1798

To the Editor of the SCIENTIFIC AMERICAN

In connection with the letter published in your issue of September 18th it may be of interest to cite an earlier suggestion of invading England by balloon In R. P Hearne's Aerial Warfare a copy of a print of 1798 is reproduced from the collection of Capt. Baden Powell, and this print bears the following inscription

The Grand Republican balloon intended to convey the Army of England from the Gallic shore, for the purpose of exchanging French liberty for English happiness! Accurately copied from a plan presented to the executive directory by Citizen Monge'

The Grand Republican balloon is depicted as having a spherical gas bag to which is suspended, by means of rope ladders a peculiar contrivance half ship and half house On top of the gas bag is the Gallic cock holding a tri-color surmounted by a liberty cap Half way down the sphere is a great circle on which is encamped a detachment of troops and a guillotine. Pipes to let out the inflammable air also appear while a pair of ornamental wings are noted A small captive balloon to serve as a boat is fastened to the great circle from which a lighthouse juts out.

The lower portion is a jumble of houses and sails with apartments for the officers in the hold Below this again is the magazine suspended by cables while a box like structure on one side bears the designation of water closet." The print bears the mark of a London publisher and forms an interesting addition to the cartoons of that period

GERALD ELLIS CRONIN

The operation of the 1,200-volt direct-current system of interurban railway control is dealt with by Mr C D Eveleth in a paper read before the Street Railway Association of the State of New York Four lines have adopted the system in America The obvious advantages assuming that there are no drawbacks which Mr Eveleth sets out to demonstrate are that the first cost is low maintenance is not more expensive and extensions to existing lines can be entered upon with much more ease and confidence. There are now in operation or under contract eleven systems of 1 200-volt direct-current railways, employing motors of 50 75 and 150 horse-power, and Mr Eveleth predicts that in a few years the 1,200 voltage will be as common as 600 The cars can be easily operated on 600 volt sections where necessary Those electrical engineers in Great Britain who still hope that the authorities will some day "encourage" the construction of rural and interurban light railways will welcome these American experiences as suggesting further sources of economy in rendering their schemes commercially attractive

THE LATEST SUBMARINES OF THE UNITED STATES NAVY

As in all mechanical development an improved type of any particular device is an evolution from its predecessors, so in general the modern Holland torpedo boat, of which the government is now building a number, is a [illegible] of the original [illegible] of that name which first made its appearance at the close of the Spanish war.

The dark object in the center is the conning tower. The periscope to which the flagstaff is attached projects above water when the boat is submerged, and by its means the commanding officer can view surrounding objects as clearly as though he looked through a field glass at the surface.

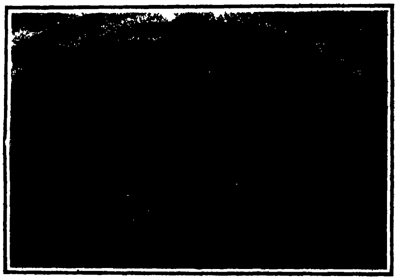
Submarine beginning to dive

These engines are used only in traveling at the surface. They can drive the boat at 14 knots. For submerged work they are uncoupled and the boat is driven by two electric motors. The latter take their energy from storage batteries which have been charged by the gas engines.

One of the twin internal-combustion engines of the submarine.

To right and left are the electric motors which drive the boat, when submerged, at 10.5 knots per hour

Looking aft in engine room



In the center are the two torpedo discharge tubes. To the left is the electric motor and gear by which the doors in the bow of the submarine are opened for discharge of torpedoes.

View on main floor looking forward

The hand wheel to the right operates the diving rudders used for steering in a vertical plane. In front of the wheel is a gage whose pointer shows the depth in feet of the boat below the surface. The curved dark line below pointer is a spirit level which shows the inclination of the boat.

Diving wheel and depth pressure gage

This shows the roof, not the floor, of the submarine interior. The horizontal eyepiece and the vertical telescope tube are rotated by means of the hand-wheel whose pinion engages an internal gear ring.

Eyepiece at bottom of periscope

THE LATEST SUBMARINES OF THE UNITED STATES NAVY

The form of hull is generally described as cigar shaped. It is built of the very best quality of mild steel and the workmanship is of the highest order, for the reason that every seam and rivet must be perfectly tight in view of the service which the boat is called upon to perform. Not only do vessels of this type undergo all the stresses of sea and weather which other vessels are subjected to, but in addition they are required to navigate at considerable depths below the surface of the water. At these depths the pressure of the water is great, so that the hull must be made sufficiently strong to withstand it.

Up to the present it has been found that the most efficient size for a boat is about 140 feet long and 14 feet in diameter. With such dimensions a boat can be built which will fulfill all requirements which the naval authorities of the world demand from it. That is to say, it can cruise on the surface for long distances at a speed of fourteen knots. At lower speeds its radius of action extends to several thousand miles. For submerged work large storage batteries are provided, which furnish energy sufficient to drive the boat from ten to eleven knots for a period of over an hour. The same electrical energy will drive her at a lower speed for a much longer time. The latest submarines built for the government by the Fore River Company at about five knots speed can run completely submerged with nothing visible above water, for a distance of 150 miles.

There are two distinct conditions in which the boat may be used. In the first, commonly known as the surface condition, the boat is prepared for cruising. A considerable portion of her hull is above water, a removable navigating bridge is in place, and she is driven by large powerful internal-combustion engines. Under these conditions she is managed in about the same way as any vessel built to run upon the surface. As for sea-going qualities, our submarines have been found in practice to be excellent. In ordinary weather they are fully as comfortable as any surface craft of the same dimensions, and even in the heaviest weather they are entirely seaworthy.

The second distinct condition exists when the boat is submerged. To pass from the surface to the sub-

(Continued on page [illegible].)

AN ALL-SEEING EYE FOR THE SUBMARINE.

Vision under water is limited to but a few yards at best, and hence a submarine boat when submerged would be as blind as a ship in a dense fog and would have to grope its way along guided only by chart and compass, were it not for a device known as a periscope, that reaches upward and projects out of the water enabling the steersman to view his surroundings from the surface. Of course the height of the periscope limits the depth at which the craft may be safely sailed. Nor can the periscope tube be extended indefinitely because the submarine must be capable of diving under a vessel when occasion demands But when operating just under the surface where it can see without being seen the craft is in far greater danger of collision than vessels on the surface because it must depend upon its own alertness and agility to keep out of the way of other boats. The latter can hardly be expected to notice the inconspicuous periscope tube projecting from the water in time to turn their great bulks out of the danger course

The foregoing article describes the type of periscope now in common use on submarines and one of the engravings on this page clearly illustrates the principles of the instrument A serious defect of this type of instrument is that the field of vision is too limited The man at the wheel is able to see under normal conditions only that which lies immediately before the boat It is true that he can turn the periscope about so as to look in other directions but this of course involves considerable inconvenience On at least two occasions has a submarine boat been run down by a vessel coming up behind it

As long as the submarine has but a single eye it would seem quite essential to make this eye all-seeing and, since the two lamentable accidents just referred to an inventor in England has devised a periscope which provides a view in all directions at the same time This has been attempted before but it has been found very difficult to obtain an annular lens mirror which would project the image down the periscope tube without distortion The accompanying illustrations show how this difficulty has now been overcome While we will not attempt to enter into a mathematical explanation of the precise form of the mirror lens it will suffice to state that it is an annular prism The prism is a zonal section of a sphere with a conoidal central opening and a slightly concave base All the surfaces however are generated by arcs of circles owing to the mechanical inconvenience of producing truly hyperboloidal surfaces. The lens mirror is shown in section at *A* in Fig. 1 The arrows indicate roughly the course of the rays into the lens and their deflection from the surface *B*, which is [illegible] curved. The tube is provided with two objectives *C* and *D* (Fig 3) between which a condenser *E* is interposed at the image plane of the lens *C* At the bottom of the periscope tube the rays are reflected by means of a prism *F* into the eyepiece Two eyepieces are employed One of low power *G* is a Kelner eyepiece the purpose of which is to permit inspection of the whole image while a high powered eccentrically placed Huyghenian eyepiece *H* enables one to inspect portions of the image The two eyepieces are mounted in a rectilinear chamber *I* which may be rotated about the prism at the end of the periscope thus bringing one or other of the eyepieces into active position The plan view Fig 4 shows in full lines the high powered eyepiece in operative position while the dotted lines indicate the parts moved about to bring the low powered eyepiece into use A small catch *J* shown in Fig 3 serves to hold the chamber in either of these two positions The high powered eyepiece is mounted on a plate *K* which may be rotated to bring the eyepiece into position for inspecting any desired portions of the annular image The parts are so arranged that when the eyepiece is in its uppermost position as indicated by full lines in Fig 3 the observer can see that which is directly in front of the submarine and when the eyepiece is in its low position as indicated by dotted lines he sees objects to the rear of the submarine. With the eyepiece at the right or at the left he sees objects at the right or left respectively of the submarine The high powered eyepiece is slightly inclined so that the image may be viewed normally and to equal advantage in all parts Mounted above a plain unsilvered portion of the mirror is a scale of degrees which appears just outside of the annular image A scale is also engraved on the plate *K* with a fixed pointer on the chamber making it possible to locate the position of any object and rotate the plate *K* so as to bring the eyepiece *H* on it The scale also makes it possible to locate the object with respect to the boat

This improved periscope is applicable not only to submarine boats but for other purposes as well such as photographic land surface work in which the entire surroundings may be recorded in a single photograph The accompanying photograph taken through a periscope of this type shows the advantages of this arrangement and gives an idea of its value to the submarine observer when using the low powered eyepiece Of course by using the other eyepiece any particular part of the view may be enlarged and examined in detail

FORMS OF PERISCOPES FOR SUBMARINES THE EYE THAT LOOKS IN ALL DIRECTIONS AT ONCE

Red and White Meat.

The flesh of cattle sheep horses wild hogs deer hares pigeons ducks geese and salmon is red or dark colored while the flesh of calves domestic hogs rabbits trout pike eel flat fishes lobsters and crabs is white or pale In fowls white meat is found in the breast dark meat in the legs and thighs The contrast is most sharply marked in wild fowl In frogs on the contrary the legs are white and the rest of the flesh is dark The mackerel the eel and many other kinds of fish also have both white and dark flesh

Knobloch has shown that this anatomical distinction between white and dark muscles runs parallel with the distinction between agile and sluggish muscular fibers which has been established by physiological experiment In general pale muscles are more active than dark or red muscles They contract more quickly but they become fatigued sooner than the dark muscles because they produce in performing the same amount of work a larger quantity of lactic acid which is the fatigue product of muscles The two classes of muscular fibers differ also in sectional dimensions The adductor or shell-closing muscle of the mussel consists of a white and a gray portion which can be clearly distinguished from each other and the presence of both kinds of fibers is explained by the habits of this mollusk

The mussel propels itself through the water by quickly opening and closing its shell but in the presence of danger it keeps its shell closed for long periods The rapid swimming movements are started by the pale and agile muscular fibers and maintained by the automatic operation of the dark sluggish fibers which also serve to hold the shell closed The same biological law of division of labor appears to govern the character of the muscular structure of higher animals The relative proportions of pale agile fibers and dark sluggish fibers are determined by the method of locomotion The incessantly leaping frog possesses a much larger proportion of white muscle than the slowly creeping toad The leg muscles of fowls are dark because the legs almost continually support the weight of the body but the breast muscles are white because the wings are used only occasionally and for short periods The dove continually on the wing has dark-colored breast muscles The flesh of the sportive calf and lamb is white while that of the contemplative cow and sheep is red The ever active heart and respiratory muscles and the very frequently used muscles which move the eyes and jaws are red The flesh of calves and lambs and the white legs of young chickens darken with advancing age Knobloch infers that the white muscles represent the primitive stage through which every dark muscle has passed.—Prometheus

COL JOHN JACOB ASTOR'S NOVEL STEAMSHIP CHAIR

Many people in crossing the ocean have experienced inconvenience by reason of the fact that the chairs in the saloon and card rooms are rigidly screwed to the floor The chairs are secured at such a distance from the tables that they will accommodate persons of very large proportions and therefore when a comparatively thin person occupies a chair he finds it necessary to sit merely on the edge for should he endeavor to lean back in the chair he finds himself too far from the table

While recently returning from Europe Col John Jacob Astor conceived of a very simple and practical scheme whereby the chairs may be firmly held in place at any desired distance from the tables or may be easily released and moved about Col Astor s scheme involves the use of a vacuum cup beneath the chair and so mounted that it may be pressed into engagement with the deck or floor to hold the chair by suction or the vacuum may be broken the cup lifted and the chair released

If the chair is on a deck or hardwood floor or on rubber tiling the vacuum will hold indefinitely while if used on a carpet it will probably be necessary to depress the cup and raise it again occasionally to form a new vacuum This device will undoubtedly add greatly to the comfort of the traveling public as chairs may then be quickly and securely fastened at the desired distance from the table to accommodate either fleshy or thin persons Col Astor intends to present this invention to the public as has been his custom with all his recent inventions

Gold Dredging in Alaska.

BY GEORGE E WALSH

The continued exploitation of new gold fields by the big gold dredges in different parts of the world has given to this industry many new points of economy which the companies are taking advantage of The great districts where the gold dredges have been in most successful operation are Australia California and Alaska In both of the former places the wholesale dredging of the ground by the mammoth gold ships has caused some trouble with the official authorities and the question of restoring the dredged fields to something like their former condition has been adjudicated in the courts

In Australia the work of reclaiming the dredged ground has been accomplished by advance stripping of the surface soil so that this can be separated from the coarse sand and silt from below The surface soil is first stripped and deposited in separate places before the gravel is touched and then after the dredging is completed the surface soil is replaced so that the land can be used for other purposes In California where the gold ships threatened to interfere with the flow of the rivers the dredging companies have been compelled by the State authorities to restore the dredged land in certain districts so that the normal water flow will not be interrupted

No such trouble however is found in Alaska where gold dredging has been carried on extensively in the past year or two Alaska is more suited to this form of gold mining than any other country and great stretches of river soil await the companies with dredges When the first big gold dredge was shipped to Alaska in sections and then assembled there it was looked upon as a very uncertain investment Owing to the short open season when the dredges could be operated and the great cost of getting the dredges into the distant mining regions it was not looked upon with favor by capitalists

Subsequent events and experience have changed all of this In the first place the enormous area of gold land suitable for bucket dredging makes it possible for the gold ships to operate indefinitely without being transported to new regions In fact the field is almost inexhaustible Consequently the investments in the big dredges cannot prove other than very profitable even if for the first year or two they could make little But even with the comparatively short open season when the ground is not frozen hard the gold ships have proved extremely profitable and the fleet up there has steadily increased from year to year

In California where the gold dredges can be operated the year around the dirt yields on an average only 15 cents per cubic yard and yet with this low yield the work is very profitable On the other hand the placer fields of Nome run from $1 to $20 per cubic yard which accounts for the fact that the dredges make more money in their short summer season than the California dredges can do in twelve months of the year A five foot bucket dredge can wash as much gravel as 3 000 men can do by hand and consequently it can secure a profit on dirt so low in grade that hand washing is utterly impossible

There are more than a dozen gold dredges now in operation in the Nome district, and every one of these is earning big profits The Guggenheims of New York have been operating three dredges for several years and several new ones are now in the course of construction The Nome Gold Dredge and Power Company composed chiefly of New York capitalists and engineers has installed several more dredges in the Nome district This concern owns or controls nearly 2 000 acres of placer ground which on a low estimate yields about $3 50 of gold per cubic yard

It costs about $120 000 to get one of these dredges up in Alaska and ready for operation in the placer district but such a dredge will yield a net return of nearly $600 000 per year Such enormous returns on the investment certainly justify the installation of new dredges. A dozen such dredges now in operation in Alaska yield annually several million dollars worth of gold and most of this is reclaimed from districts that the hand operating companies overlook. The craze for new districts that yield enormous returns continues to attract the average miner and he passes over unnoticed the placer mines that prove rich harvests to the dredge companies There is no interference by State authorities with dredging in Alaska and no thought or consideration of restoring the surface after operations enters into the calculations of the companies

The character of most of the gravel in the Nome district makes it ideal for either dredging or hydraulicking It is almost entirely free of large bowlders clay substances and roots which might obstruct the operations of the dredge or sluicing apparatus The placer lands lie for the most part in valleys between sloping hills This land is covered with snow early in the fall and thus prevents hard freezing As a result dredging operations can begin as early as the first half of June and continue fully four months or for about 120 days This makes a season s work and then the dredges have to stop operations for the long winter It seems like a very short season for mining operations but owing to the character of the soil and the gold yield it proves very profitable

COL JOHN JACOB ASTOR S IMPROVED STEAMSHIP CHAIR.

Before an investment is made in a gold dredge of this character the placer land is first carefully investigated and the probable gold output estimated Thus before the first dredge was shipped to Alaska upward of a hundred shafts were sunk to depths ranging from 10 to 15 feet and the lowest yields of gold were found to be $3 50 per cubic yard while in the river beds the gold often ran as high as 1[illegible] cents per pan or over $20 per cubic yard

Except at the foothills the dredge companies around Nome have never yet struck bedrock and the lowest shaft put down was 15 feet in depth Further sinking was prevented by the shafts filling with water but from every indication the bedrock is at least 25 to 30 feet below the surface This bedrock is composed of mica schist and slate. In all the dredging operations of these placer mines, the values increase more steadily at bedrock than at higher points and even from 6 to 18 inches into the bedrock the returns are large. The whole character of the land is ideal for dredging and there is plenty of water for as many dredges as could possibly be used

The fact is the coming of the big gold dredges in Alaska and their successful operation, with unlimited possibilities for work for many years to come, has marked a new era in mining for the precious metal in this far northern country It is the beginning of the end of aimless unscientific gold mining. The great finds of gold where prospectors can pick up gold in quantities are no longer so common as a few years ago The field has been pretty nearly investigated and the character of the mining must change to suit new conditions This means that the influx of fortune hunters will gradually cease, and mining will fall into the hands of companies who are willing to get their returns gradually through improved, though somewhat expensive methods of work A great many owners of ordinary placer claims are today renting out their land to gold-dredging companies and others are organising for the purpose of installing their own dredges Taking the returns for a period of five or ten years the profits of a gold dredge company are infinitely higher than another which depends entirely upon making rich finds and then gathering the surface gold for quick returns Gold dredging in Alaska is thus an infant but lusty industry and its growth in the next few years must be phenomenal and steady

Has the Earth's Climate Changed in Historic Times?

The explorations in Central Asia have laid bare the ruins of once flourishing cities M Boutquin in the French journal Ciel et Terre proves by historical evidence and modern scientific discoveries, that the abandonment of these regions by the human race was brought about by causes entirely unrelated to such supposed meteorological changes as a general cooling of climates or a progressive desiccation of the globe In Europe, for example a sensitive lowering of the temperature and decrease in the precipitation of rain and snow would have caused a well marked and continuous recession of glaciers but no such recession is shown by the records of more than two thousand years. Heim has proved that although the glaciers of the Alps receded during the latter half of the nineteenth century they are now far more extensive than they were in the Middle Ages

Polybius in the second century B. C described the rich gold and silver mines of the Tyrol These mines yielded abundantly until the middle of the sixteenth century after which date their productiveness rapidly diminished because the mouths of shafts became covered with ice A shaft sunk at this epoch was covered in 1570 by a glacier 65 feet thick Resistance to the invasion of the ice soon became impossible In the eighteenth century the glacier was more than 300 feet high and in 1875 it had attained a height of 460 feet

For many years it was asserted that the east coast of Greenland had formerly enjoyed a mild climate which favored the growth of vegetation and gave rise to the name Greenland The historical researches of Rink and Von Maurer however have proved that the decay of the posts established by the Norwegians in olden times was caused by the introduction of a contagious disease and by the adoption by the Norwegian government of an unwise economic policy which provoked hostile attacks by the Eskimos Equally erroneous statements have been made in regard to Iceland

In the British Isles the cultivation of wheat formerly extended much farther north than it does at present simply because it was then in the absence of foreign competition, more profitable than it is now Yet it has been very difficult to gain acceptance for this elementary truth the popular belief in a change of season or climate for a long time prevailed over all evidence

In Belgium and other countries also agriculture has been radically transformed by the operation of economic laws improved methods of culture, and a more intelligent choice of crops. In the Middle Ages and until the fifteenth century the vine was cultivated in Bavaria and in other parts of Germany from which it has now almost entirely disappeared, but its disappearance is not due to climatic changes The wine produced in these districts was generally of inferior quality and with the growing refinement of taste it was gradually supplanted by foreign wines and good native beer

The culture of the vine has practically disappeared from Belgium for similar reasons Two Belgian abbeys still possess vineyards and make wine for sacramental use In France it has been proved that the vintage season has not shifted appreciably since the fourteenth century It has likewise been demonstrated that contrary to the popular belief the vine was never cultivated in Switzerland except on a very small scale in gardens, and [illegible]

Handy Man's Workshop

AN EASILY CONSTRUCTED EQUATORIAL MOUNT FOR SMALL TELESCOPES.

BY PROF. R. W. WOOD, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

In the course of some experiments which I have been making at my summer laboratory in East Hampton, Long Island, on the photography of the moon in ultra-violet light (=3,100 — 3,200) it became necessary to provide an equatorial stand with a slow motion screw for accurate following. As a polar axis is often desired in a hurry for special work, and as there are doubtless many amateurs who sometimes feel the need of such a stand, it seems worth while to give a short description of a very efficient, though hurriedly improvised, one which I constructed for my purpose.

THE SLOW-MOTION SCREW.

It was made from the frame of a discarded bicycle, the bearings of the steering rod being, however, in good condition, with little or no lateral movement. The wheels, sprockets, saddle etc., were removed and the frame stood up in a wooden box, in such a position that the steering axis was approximately at the latitude angle. The box was then filled with Portland cement (1 part cement with 3 parts of clean sand and sufficient water) which was allowed to solidify The larger places were filled with bricks and rock fragments to economize the cement A day or two is sufficient for the solidification, after which the box can be knocked to pieces, leaving the frame rigidly mounted in a solid and very massive block. This block was placed on a small brick pier and the adjustment of the polar axis made by blocking up one end of the cement base. A short piece of 2 x 4 inch joist was lashed to the handles of the bicycle with strong wire, which served as a support for the declination axis. The rest of the stand is to be designed according to the use to which it is to be put. In my own case I required merely a device which would enable me to keep my quartz telescope pointed accurately at the moon for two minutes From odds and ends which had accumulated in my shop the arrangement shown in the illustration was built A short plank was mounted on the 2 x 4 on a horizontal steel axis turning in brass bearings. To the forward end of the plank a rod was fastened which passed through a wooden block clamped between the lower ends of the front forks with a small bolt This block could be turned to suit the elevation of the telescope, and the rod fastened with a "set-screw," shown by an arrow in the picture

Slow motion about the polar axis was accomplished by a brass rod, hinged to a larger piece of rod which fitted into the T tube which formerly carried the saddle. A small piece of brass tubing was soldered to a small piece of ¼ inch sheet brass, through which passed the slow-motion screw, sharpened to a point and turned by a small wooden wheel, made from a spool (indicated by an arrow) The brass tube and screw could be clamped at any point on the long brass rod by means of a set-screw The point of the slow-motion screw turned in a small conical pit in a piece of brass fastened to the end of the 2 x 4 joist. The weight of the instrument being carried on the handles, that is, above the polar axis, the instrument always tended to turn (by gravity) upside down, except when pointed at the meridian This it was prevented from doing by the pressure of the point of the slow-motion screw, and by turning the screw either forward or backward according to whether the instrument was pointing east or west of the meridian, a very uniform rotation about the polar axis was secured. A diagram of the slow-motion screw is given in the accompanying line drawing.

The instrument was set approximately in the meridian by sighting the pole star in line with the edges of the two front tubes of the diamond frame The proper elevation of the polar axis was secured by trial, observing whether, in following the moon it moved up or down in the field of the telescope In half an hour I got the thing in such shape that I could keep the center of a small crator on the point of intersection of the cross hairs of the telescope for ten minutes, and as this was more than the required accuracy I let it go at that. The instrument as constructed works admirably except when pointed at the meridian. On passing the meridian the slow motion screw is carried over to the other end of the 2 x 4 joist, this movement being allowed by the hinge at the end of the rod When accurate following is not necessary, that is, when it is merely necessary to keep the object in the field, a more convenient arrangement would be a brass cog wheel attached to the steering rod below the handles, and turned by a worm wheel this would obviate the trouble when crossing the meridian It would not, however, give such uniform motion as the arrangement described, unless accurately and carefully made

For mounting a small telescope any device can be used which will permit the instrument to swing up and down in a plane.

It is quite remarkable how well the old bicycle frame lent itself to the construction of the stand The front forks which hold the "elevation" fixed and the saddle tube for supporting the slow motion rod could hardly be improved upon if made for the purpose

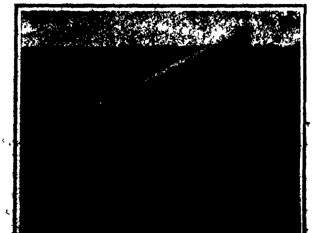
* * *

ALTERNATING CURRENT EXPERIMENTS.

BY FREDERICK E WARD

Students and amateurs who like to make electrical experiments are particularly fortunate if they have alternating current lighting service in their homes as the alternating current lends itself especially well to the performance of easy experiments that are at the same time both amusing and instructive Of the many kinds of experiments that may be made with simple apparatus there are perhaps no others that are more interesting than those which illustrate the principles of the rotary magnetic field and its application to electric energy meters and to induction motors.

For making the necessary apparatus there are required two similar laminated iron rings about 3½ inches inside diameter, 4½ inches outside diameter and ¾ inch thick. These may be built up by coiling up a sufficient length of thin sheet iron strips cut ¾ inch wide, using a round wooden block to start on Compact iron wire bundles of about the same dimensions may be substituted with good results or better than either of the above, rings made up of a sufficient number of thin sheet iron punchings. After the rings are made, all sharp edges should be rounded off with a file and a smooth covering of cotton tape be applied as shown in Fig 1, A.



If there is any choice between the two rings, select for the field the one that comes nearest to being a true circle on the inside For the winding on this ring use No 23 or No. 24 double cotton-covered magnet wire. Have the wire on a spool small enough to pass through the ring easily and begin at any point such as B, Fig 1 Wind the wire in a single layer with turns as smooth and close as possible on the inner circumference, until exactly one-quarter of the latter has been covered. Next reverse the direction of winding as shown at C Fig 1 and cover the second quarter of the ring by passing the spool through in the opposite direction, after tying down the little loop at C with a piece of thread. Make similar reversals at the half and three-quarter points, and cut off the wire near the place of beginning This completes one-half of the winding The second half is to be wound on top of the first half, and is to be similar in all respects except that the place of beginning must be shifted to a point 45 deg. away, as at D Fig. 1.

The second ring, which is for a reactance, is to be wound with 600 turns of magnet wire of any size larger than No. 20. This winding must not have any reversals in it, all of the turns being passed through the ring in the same direction.

Lay the two rings down flat on a piece of board and make connections to a 110-volt 60-cycle supply circuit as shown in the diagram in Fig. 1, where S indicates a snap switch or knife switch, and L, L, L, L four 16-candle-power 110-volt lamps. When the switch is closed current flows through the two windings on the field ring in such manner as to produce four magnetic poles that are not stationary but rotate or progress around the ring 1 800 times per minute A pocket compass placed close to one side in the field as shown will rotate at this speed and illustrate the principle of the synchronous motor in which the magnetized rotor is dragged around by the rotating magnetic poles of the field just as positively as if it were geared directly to the dynamo If the compass be placed close to the ring on the outside, it will turn in the opposite direction The field can be reversed by exchanging the connections to either one of its two coils

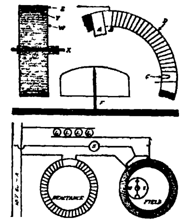


Fig 1 —DETAILS OF THE EXPERIMENTAL APPARATUS

To show the poles made by the field lay a sheet of white paper on the ring and sprinkle some fine iron filings on it while the current is on It is not so easy to show the movement of the poles in this way but it may be done as follows Shake some very fine iron filings through a piece of cloth on a sheet of paper and then hold up the latter by one corner The larger particles will slide off and only the very finest will cling fast like dust Lay the paper on the ring while the current is off and close the switch for the briefest possible moment Do this several times in succession and considerable movement of the particles will be observed

Drive a large pin through a piece of wood as shown in Fig 1 F, and balance on the point a brass box cover or bell so that the latter is free to turn If the magnetic field be then placed around the bell the latter will be slowly dragged around by reason of the eddy currents set up therein and will illustrate in part the principle of the driving mechanism of some forms of integrating wattmeters Observe how the speed of the piece of brass varies in proportion to the number of lamps that are lighted at L

If an iron (tin) box cover be substituted for the brass one the speed will be higher and the pull more vigorous, illustrating the principle of the induction motor If an empty tin can be thus supported in the field, it will be rotated with considerable force and soon get off the pin Fig 2 shows how the field may be supported in a vertical position and provided with a better rotor from which it is possible to get enough power to drive light toys The details of the rotor are shown in Fig 1 where W is a turned wooden support provided with a small shaft X and having in its periphery an iron hoop Y over which is slipped a copper hoop Z To be efficient the rotor must be made of a diameter as large as possible without touch

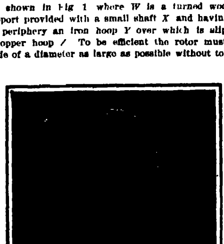

Fig. 2.—ALTERNATING CURRENT MOTOR.

ing the windings of the field It should be made to run true, and turn easily on its shaft.

The performance of the above experiments and of others that will be suggested by them can be made more interesting by studying the reasons why from some good textbook on the elements of alternating currents to which the reader is referred for a fuller explanation of the principles involved

DEVICE FOR REMOVING WOOD SCREWS.

BY JAMES PATERSON

In the Handy Man's Workshop department of July 31st a device for removing wood screws was described which struck me forcibly Another device for the same purpose has been designed by William Laycock, a weaving section hand in the Arlington Mills of Lawrence, Mass Quite often screws in the shuttle springs for holding down the spindle will break and the difficulty formerly was to get out these screws without injury to the shuttle, so Mr Laycock bethought him of an old screw-driver spindle, cut the point off, and then with a hacksaw cut two grooves in it at right angles as indicated in the illustration The grooves were made as wide as possible and fairly deep, leaving the edges sharp In use the tool thus prepared is pressed against the broken piece of screw and digs into it sufficiently to permit of turning and thus removing the screw

DEVICE FOR REMOVING WOOD SCREWS.

MENDING A BROKEN METALLIC FILAMENT

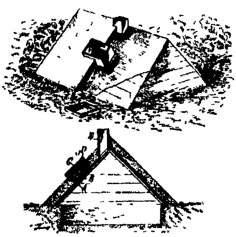
BY HOWARD W NICHOLS.

A carbon filament incandescent lamp, when the filament breaks, is of no further value, but in the case of a tungsten or tantalum lamp it is often possible to mend the filament so that the lamp will be nearly as good as new Place the lamp with the broken filament in a socket which is connected to the lighting circuit by a flexible lamp cord Turn on the current and gently shake the lamp so that the broken ends of the filament will strike against the main part and draw a small arc which will weld them securely to it and thus allow the current to pass through the filament, lighting it up brighter than before breaking This mending process usually cuts out only a small section of filament but if a comparatively large portion of the filament should happen to be cut out of the circuit, it would reduce the resistance of the remaining filament to such an extent that an excessive current would flow and thus soon burn the filament out. However while it lasted, the lamp would give a very bright light.

A SIMPLE FRUIT CELLAR.

BY F A. KAISER.

Doubtless many readers of the SCIENTIFIC AMERICAN have found it difficult to keep apples and the produce of their gardens such as carrots beets turnips, celery, etc, in perfect condition until they could be used. The accompanying drawings show a cheap and easily made fruit cellar in which I kept twelve bushels of apples besides carrots, squashes, and potatoes, from October until April My house was six feet wide, eight feet long and six feet high, and cost me about $4 Smaller ones can be built for a proportionally smaller sum.



A SIMPLE FRUIT CELLAR.

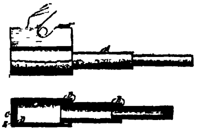
I dug a hole about eighteen inches deep and set the house over it, as shown in the cross section. The entrance is made like a box about twelve inches deep, so that soil or manure can be spread over the roof to a depth of about ten inches. Cleats *A* on the inside of the opening hold slats *B* at the bottom of the box opening. In the space *C* I stuff an old tick filled with straw or leaves Outside cover *D* protects the tick from moisture. The rafters should be about two inches square, or 1 x 2. Provide a chimney, *E* (of wood), which must be stuffed with straw during zero weather The chimney is not absolutely necessary, as the house can be ventilated through the door during mild weather The proper slant for the roof is about 45 deg., as earth can be packed on at that slope. Cover the roof with a cheap grade of building paper, or with newspaper, before putting on the earth, but do not use a paper that has a strong smell, like tar paper

I have had this house in use now during three winters, and it has saved me more than its cost every year Apples and vegetables keep fresh and plump in it, and do not shrivel up as they will in an inside cellar

HOW TO MAKE A PAPER TELESCOPE BARREL.

BY C. R. M'CARTY

The making of a paper telescope barrel is shown in the accompanying illustrations. First we make a wooden mandrel, *A*, that represents the various reductions in the barrel of the instrument. These portions of the mandrel are made of such diameters as to bring the interior of the barrel to the proper size Wrap on a layer or so of paper having a dull black finish so as to keep down any reflection of the rays of light on the interior of the instrument. When several layers of this paper have been carefully applied, Manila paper such as used by draftsmen in making pencil drawings should be laid on over it. It is understood that this paper is laid with glue between each layer, and this can be done to best advantage with the wooden mandrel placed between lathe centers. When the paper has been wrapped on to a thickness of about ¼ inch we shall have good substantial tubes. The exterior may be varnished or covered with cloth or paper of fancy pattern The stop pieces are simply rings laid on as shown at *B* When these stop rings have been placed in position the ring *E* is applied and glued fast, after which the lens is fitted against it and a second ring *F* is applied to hold it in place.



A PAPER TELESCOPE BARREL

These rings must be of dull black finish The eyepiece may be applied in the same way This makes a most excellent case for a telescope

RESTORING A DRY CELL.

BY DR. EDWARD H HANSON

Having experienced a great deal of trouble with the usual small cell batteries such as are used for medical wall plates, gasoline engines etc I have experimented until I have discovered a very simple method of restoring the ordinary dry cell sal ammoniac battery My method is as follows Midway between the carbon and zinc at the top of the battery drill a hole 3/16 inch in diameter down to within 1½ inch of the bottom of the cell On the opposite side drill a hole through the sealing wax covering 1/16 inch in diameter and 3 inches deep Place a small glass funnel in the large hole with the stem at least 2 inches long Into this pour one ounce C P hydrochloric acid After this is thoroughly absorbed pour in the funnel one ounce of water When all is absorbed seal the holes with ordinary stationer's sealing wax After twelve hours it will be found that the batteries so treated will work with increased voltage and amperage over a new dry cell. They will work well on either closed or open circuit and have from four to six times the life of a new dry cell I am using a series now that I employed in my office for three years and during that time have renewed them three times The batteries will work until the zinc pole is completely exhausted if the chemical elements are kept at the required strength by renewal

THE HANDY MAN'S SUB-CALIBER GUN.

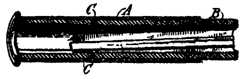
BY AUGUST MENCKEN

Those familiar with heavy artillery know that sub-caliber work forms a very important part of the drill Very accurate work can be done by this method, but of course the range is very much shortened and the recoil and noise are missing.

Anyone having a large-bore rifle, such as the old model Springfield, and wishing to use it for short-range or gallery shooting, can sub-caliber it very easily in the following way

Take an empty regulation shell and bore out the head so that its inside diameter will be the same throughout its length. Then take a 0.32 caliber 3-inch revolver barrel—the hexagonal kind used in cheap revolvers is good enough for this purpose—and turn it up until it fits in the shell snugly but not so tightly as to swell the shell. Then carefully chamber the barrel to take the 0.32 cartridge. Great care must be taken in doing this, as the accuracy of the gun depends greatly on this part of the work. Next countersink the revolver barrel, *B*, so that the head of the 0 32 will lie flush with the head of the regulation shell *A*, as shown in the illustration. If this is not done the breech will not close and the shell may be accidentally exploded. Pins, *C*, should then be driven through the shell and barrel to keep the latter in place. This will not be needed if the barrel and inside of the shell are slightly tapered, the taper increasing from the muzzle end to the breech.

For ranges from 25 feet to 100 feet this method will work very well, and if the rifle is built so that a longer barrel could be inserted, of course its range would be increased.



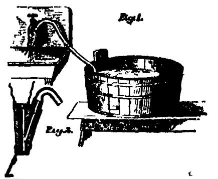
THE HANDY MAN'S SUB-CALIBER GUN.

A DEVICE FOR EMPTYING A TUB.

BY G. W FAIRBANK.

Considerable difficulty is often experienced in emptying and refilling the common form of movable washtubs. Stationary washtubs are usually provided with suitable plumbing connections whereby the water may be easily and quickly drained off, but with the ordinary form of wooden movable washtubs the entire tubful of water must either be lifted and carried to the sink or other drain to empty it, or the water must be bailed out of the tub and carried to the sink or drain by the pailful The lifting of the tubful of water is often a physical impossibility, and the carrying of the water from the tub to the sink by the pailful is a tiresome task If the house be provided with running water at the sink, a very simple contrivance may be devised for utilizing the city water pressure for the emptying of the tub By providing a simple form of ejector at the faucet and connecting one inlet of the ejector to a short piece of hose leading to the sink the water may be very easily drawn out of the tub into the sink, even though the latter be at a higher elevation In the accompanying sketch, there is shown a simple contrivance of this character, in which the ejector is formed of a block of wood adapted to be detachably secured to the faucet. The ejector includes two passages intersecting at an angle and having a common outlet as shown in section in Fig. 2 One of these passages receives a stream of water under pressure from the faucet, and the escape of this water from the lower end of the ejector tends to draw water out of the tub through the hose and to deliver the latter to the sink.

The same device may be used for refilling the tub. To secure this object, it is merely necessary to close the lower end of the ejector with a plug or in any other suitable manner As shown, a short rubber plug is connected to a strap tacked to one side of the block By inserting the plug within the open lower end of the passage and securing the free end of the strap to a button on the opposite side of the block, as shown in dotted lines the water will be caused to flow from the faucet down through one passage and up through the other to the hose and thence to the washtub.



HANDY METHOD OF EMPTYING A TUB.

* * *

An interesting experiment to determine whether the strength of iron and steel was affected by magnetism was carried out at the Technical Institute of Belfast with the following reported result Bars of mild steel and wrought iron 8 inches long by ½ inch to 1 inch in diameter were used, part of which were magnetized by being saturated in a solenoid. When tested, the elongation of the magnetized parts decreased [illegible] per cent, and the average breaking load [illegible] increased.

RECENTLY PATENTED INVENTIONS.

Electrical Devices.

ELECTRICAL FUSE.—A. G. Fay, Highland Park, Ill. The fuse is for use in blasting, the more particular purpose being to protect the materials and containing shells of the fuse against moisture. To this end the invention relates to the addition of an outer shell and a filling, the size of the diameter of the outer shell being slightly reduced at one end therefor for sharpening the effect of detonation of the fuse.

Of General Interest.

BOAT.—F M Thompson, East Liverpool, Ohio. Among the characteristic features of this patent is a vertically rocking rudder or tail plate, the movement of which causes the prow of the boat to rise and fall in the water to a degree desired. To overcome any suction and break up formation of vacuum at the plate the latter is made hollow and means are provided to discharge air into and through. Horizontal rudders or vertical axes are provided in front of the plate and in rear of the propellers for steering.

CRATE.—D F Payne, Corpus Christi, Texas. The invention relates to crates used for shipping the more particular purpose being to provide a type of crate which may be folded readily when not in use and provided with top and bottom members detachable from other portions of the crate and adapted to be sprung into position for the purpose of holding them into position.

WINDOW.—H Mortenson, New York, N Y. This invention is an improved window, in which either the upper or lower sliding sash may be turned end for end and brought inward in the lower portion of the window frame where the outside of the sash is easily accessible for washing or other purposes, and a ventilating space between the sashes provided if desired.

RECORD-HOLDER.—W T Long, Sumner, Wash. The object here is to provide a holder arranged to accurately and securely hold the record in central position to accommodate records of different sizes, to compensate for variations of the inside diameter of the records, to hold the record against accidental shifting in an axial direction and to allow placing it conveniently in position on the holder or removing it therefrom.

EMBALMING APPARATUS.—J B. Coppola, Mexico, Mexico. An object in this invention is to provide a simple apparatus capable of holding the liquid and compressed air in a reservoir, and devices for connecting the same with trocars or needles for injecting the fluid under pressure into a cadaver.

FLASK FOR FORMING GATED MOLDS.—C W Bliss, Montgomery, Ala. This invention provides a construction of flasks wherein the gated molds may be formed in tiers and the pattern members withdrawn therefrom, provides flasks wherein the cores may be inserted from the outside of the flask and held firmly in position, and provides a flask adapted to be mounted in tiers and arranged to accommodate molds of various sizes.

DRY SEPARATOR.—R R Snowden, Houston, Texas. The invention relates to mills, and the object is to provide a separator more especially designed for treating crushed phosphate rock and other materials so that the material in a revoluble screen is subjected to alternate brushing and jarring actions, to thoroughly separate the valuable material from the extraneous matter.

SCREEN.—C J Jewett, Fort Smith, Ark. The invention relates to screens which may be used for clay, coal, or other materials, and an object is to provide a screen with adjustable screen bars, and means to move the bars to predetermined distances from each other. Means prevent the material from becoming clogged between the screen bars.

DAMPER-REGULATOR.—R. P Mitchell and R. V Brawley, Statesville, N C. A spring is adjusted to retain a disk against predetermined pressure in the boiler. Means permit the cylinder to exhaust, but should the pressure exceed predetermined value, means are provided to close or partially close the damper in accordance with the excess of pressure. A valve is so elevated that a disk closes the inlet opening to the pipe, but when pressure falls, means permit the cylinder to exhaust, the piston to move downwardly, to allow a weight to swing the damper into open position.

PARALLEL-RULER.—F W Sterling, Chicago, Ill. The invention appertains to drafting instruments, and its purpose is to provide a new and improved parallel ruler, more especially designed for the use of navigators and other persons, to permit them to accurately and quickly transfer parallel lines when translating courses on a chart.

CIGAR PERFORATOR.—R. F Hall, Fowler, Cal. The improvement is in that class of perforators which are provided with a series of opposite points or prickers pivoted and arranged convergently in such manner that when the tip of a cigar is pressed down between them they enter the same and thus form lateral holes which assist in producing an easy draft.

WINDOW-VENTILATOR.—G. W. [illegible], Chicago, Ill. The inventor provides a device by which good ventilation is secured, while at the same time the ventilating opening is shaded without the necessity of using a projecting awning or other similar device. He provides a device which while permitting good ventilation prevents the rain or snow from entering while the device is in use.

Hardware.

WRENCH.—W A. Pratt, Stamford, Conn. This wrench is adapted for screwing up or unscrewing caps or jars and other packages, and for loosening the caps from the rubber or other packing rings, it being adjusted for gripping objects of various sizes, and having handled V-shaped jaws pivotally connected with each other at their ends and a supplementary jaw adjustably and removably attached to one of the jaws to co-act with the opposite jaw.

WOODWORKER'S PLANE.—J H Brown, Boston, Mass. The intention here is to provide for a plane that facilitates the exact adjustment of the cutter bit laterally and longitudinally in the throat of the plane stock, enable the quick and exact graduation for size of the throat opening in the stock, provide means for clamping the cutter bit when adjusted in the throat opening.

TUBE-CUTTER.—O R Young, Riverhead, N Y. The invention is useful for various different purposes and particularly in facilitating the removal of defective tubes in a boiler or similar tubular structure. In a boiler access cannot easily be had to the exterior of the tube and some difficulty is experienced in removing the tube unless it be cut in two from the interior.

COMBINATION TOOL.—W J Tweedale, Saginaw, Mich. The intention in this case is to provide a wrench of ordinary construction, with attachments whereby it may be used as a pipe wrench or a drill or a turning lathe and for many other purposes. The handle may slip out of the extreme end of the shank so as to give room between the jaws for the drill bit.

Heating and Lighting.

CORE-OVEN.—J. J. Johnson, Newark, N J. The invention relates particularly to core ovens used for drying or baking cores used in molding. The object is to produce an oven which will be simple in construction, the temperature of which can be nicely regulated, and which will have a construction which will enable the oven to be kept constantly filled.

ILLUMINATING SIGN.—J F Drugas, Buffalo, N Y. This invention relates to advertising signs such as those hung out in front of stores or shops to indicate the business done therein. An object is to provide an illuminated sign which can be read at night from a considerable distance with ease and which can be equally as well read in the daylight.

Machines and Mechanical Devices.

COMPUTING PUMP.—S. G Wiss and J E. Troyer, Jr., Gas City, and J K. Smisor, Marion, Ind. The invention refers to computing pumps, and more particularly to pumps designed to be used in dispensing and selling fluids such as oil and the like. When one gallon of fluid is pumped by the pumping mechanism one gallon is registered by the computing mechanism. When one gallon has been forced through the casing, the dial has made a complete revolution.

VENDING MACHINE.—F A. Slichter, Kansas City, Mo. The aim of the inventor is to provide a machine more especially designed for use in stores and other places, and arranged to allow convenient delivery of the merchandise in predetermined quantities, without danger of packing and obstructing the rapid flow of the merchandise, such as seeds of various kinds.

AIR-SHIP.—A. E. G Lueke, San Francisco, Cal. An object here is to provide a ship having an aeroplane and a balloon or gas bag connected therewith, together with an improved steadying means. A further object is to provide a balloon composed of one or more separate gas bags inclosed within a shell or chamber having means for regulating temperature. The propellers may be caused to rotate horizontally or vertically.

FEED MECHANISM FOR BORING MACHINES.—A. Frey, Schöftland, Switzerland. The inventor provides a mechanism capable of being quickly changed for use as a hand feed or an automatic feed, and arranged to permit convenient changing of the gearing so that the feed mechanism for feeding the boring tool may be run at any desired speed according to the nature of the rock to be bored.

Prime Movers and Their Accessories.

ROTARY ENGINE.—F O Biehl, Wilkinsburg, Pa. In this case the inventor's desire is to produce an engine in which the various parts are designed to permit of exact adjustment for controlling the motive fluid to permit of utilizing the expansive force of the fluid to a greater or less degree, and has had in view the construction of an engine which will permit of the use of as many cylinders as desired.

Railways and Their Accessories.

SAFETY SWITCH LOCK.—A Haddock and A Schmitt, New York, N Y. An object here is to provide a lock which can be used in connection with various switch systems and block signal systems without interfering with the operations thereof, and which serve to lock a switch either open or closed as set by the switchman so that the switch cannot be accidentally displaced while a train is approaching the switch or passing over the same.

LOCOMOTIVE-HEADLIGHT.—I L. Wade and W L. Smith, Roanoke, Va. In the present patent the invention is an improvement in that class of locomotive headlights which are pivoted and so connected with the front truck as to be turned with the latter in passing around curves. The headlight, yoke and arms may be readily detached when required.

SNOW PLOW.—C A Bellaud, Fairdale, N D. The object here is to produce a snow plow which will effectively operate to cut the snow from the railroad track and eject it at the side. In its general construction the plow comprises a pair of cutter wheels which are mounted at a forward point, and behind these cutter wheels an apron is provided which assists in throwing the snow rearwardly into a drum from which it is discharged laterally or at right angles to the track.

Pertaining to Recreation.

SOCKET POST FOR SUPPORTING CROQUET ARCHES.—H R Collier, Prairie Grove, Ark. The purpose of this inventor is to provide novel details of construction for a socket post which adapt it in pairs for a secure embedment in the ground at suitable points in upright positions, and for the convenient insertion of the limbs of a croquet arch thereinto, and thus afford stable support to the arch in a vertical plane and permit the removal of the arch.

Pertaining to Vehicles.

AUTOMOBILE-PROTECTOR.—D F Armstrong, Groton, Conn. The invention relates more particularly to protectors such as are adapted to be arranged on the steering posts of automobiles to protect the drivers. It can be easily secured to the steering column of an automobile and fitted with either a transparent or a translucent shield to protect the driver.

WHEEL.—L. Y León, San Juan, Porto Rico. The invention relates to wheels for general use, the more particular purpose being to provide a wheel suitable for a road vehicle, and having a considerable degree of resilience due to the type of springs employed within the wheel and to the manner in which they are mounted and kept in position.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 18th or will be sent by mail on request.

(12127) A. C Co asks: We would like to get an approximate idea of the amount of coal burned by the average ocean-going vessel of 700 tons net registry drawing from 9 to 15 feet, that is to say, the amount of coal per hour burned in producing a speed of from 10 to 15 knots. A. It is impossible for us to give a reply to your question equally accurate and general for all cases, for the reason that coal consumption per horse-power varies so much with the efficiency of both engines and boilers, and horse-power for a given speed varies so much with the lines of the boat. For instance, a 700-ton yacht with fine lines might be driven at a speed of 10 knots with half the horse-power required to give the same speed to a cargo boat of the same displacement, and as the boiler and engines of the yacht might easily have 50 per cent higher efficiency (say 30 per cent efficiency as compared with 20 per cent) the yacht might make the same speed as the cargo boat with one third of the latter's coal consumption. Again every steamship has its maximum economical speed, and whereas a given quantity of coal may drive it a little greater distance at a lower speed any attempt to drive it at a higher speed will cause an increase of coal consumption out of all proportion to the increase of speed gained. There might therefore be a great difference between coal consumption at 10 and at 15 knots, and a boat of which the former was the economical speed might be unable to achieve the latter with any reasonable coal consumption if at all. Although you only ask for an approximate idea, we must therefore make this reservation to show you how widely an average figure may vary from that of your particular case. If you gave tonnage, economical speed, and horse-power we could give a fairly close figure for average lines, but knowing neither lines nor horse-power the chances of wide disparity are multiplied. With the foregoing reservation, we may say that the average coal consumption of three nominal 10-knot boats of 700 tons displacement in actual service, within our knowledge, is 9 tons per day. The horse-power of these ranges from 400 to 600 and averages 500, which represents 1.5 pound of coal per hour per horse-power, which is good marine practice for any except the most efficient multiple-expansion engines. Only one of these boats has ever been or could be driven at 15 knots, and that was as an experiment, and necessitated a consumption of 3,750 pounds of coal an hour, or nearly five times the economical consumption.

(12128) N V V says: Being a constant reader of the Scientific American I take the liberty to ask you the following question: If it takes 10 tons of coal to run a locomotive 100 miles in 10 hours, how much coal would it take to run the same engine the same distance in 5 hours? I claim that as based upon the mechanical rule, what you gain in speed you lose in power, it ought to be about the same amount. A. It is impossible to answer your question exactly without a great deal more detail as to the locomotive, the load hauled, etc., but speaking generally, the fuel consumption is likely to increase out of all proportion to the speed, if the latter is increased above the economical speed of the engine. Each engine has a certain maximum speed at which it can haul a given load economically, and whereas with a given quantity of coal it can haul the same load a greater distance at a lower speed, at a higher speed the coal consumption increases very much more rapidly than the speed. For instance, an engine burning 1,930 pounds of coal per hour at a speed of 40 miles per hour uses 3,400 pounds per hour in hauling the same train 60 miles per hour, nearly doubling the coal consumption for a 50 per cent increase of speed, and 3,920 pounds at 70 miles per hour. These are figures from an actual test, the coal consumption varying directly with the horse-power expended. In your case, however, 10 miles an hour is not likely to be the economical speed of the locomotive and it is probable that it could cover 100 miles in 5 hours with the same or very little more coal than it would take to cover the same distance in 10 hours.

NEW BOOKS, ETC.

Astronomy of the Bible. An Elementary Commentary on the Astronomical References of the Holy Scripture. By E. Walter Maunder, F.R.A.S. New York: Mitchell Kennerly, 1909. 34 ill.

Mr. Maunder's attitude toward the celestial miracles of the Bible does not differ essentially from that of the average non-astronomical Christian. He frankly regards the Bible as an inspired utterance. Although he does not hesitate to present the scientific theories which have been advanced to account for such miracles as Joshua's Long Day, the Dial of Ahaz and the Star of Bethlehem, he is more prone to consider them as divine portents rather than as ordinary astronomical occurrences. He constantly reminds us that the Scriptures were not intended to teach us the physical sciences, for which reason in his opinion it is almost futile to offer scientific explanations of Biblical miracles. In the case of the Star of Bethlehem, for example, Mr. Maunder is inclined to accept the miracle, and although he presents the usual theories of a conjunction of planets, a comet and a nova to account for the apparition, he regards the Star of Bethlehem as a specially [illegible] miracle for the guidance of the Magi.

Statistical and Chronological History of the United States Navy, 1775-1907. By Robert Wilden Nesser, Fellow of Yale College. In two volumes. The Macmillan Company, 1909. Quarto, 650 pp. Price, $12 net.

In spite of the many books that have been written on the history of the United States navy, it is the opinion of the author that the record is yet incomplete. Hence he has undertaken the task of historian upon a scale of research and completeness that leave nothing to be desired, going back as far as possible to the original authorities, and—a most important feature—giving these authorities in the text. The completed work will be divided into five parts. The first three parts, here offered, are complete in themselves, and contain data concerning every engagement, capture, expedition or other achievement of the navy prior to January 1st, 1907. The remainder of the work may be considered as supplementary. This is a monumental work carried out with great fidelity.

Nelson and Other Naval Studies. By James R. Thursfield, M.A. New York: E. P. Dutton & Co. 374 pp. Price, $4.

Unlike so much of the literature of the life of Nelson, the present work was written by a civilian. The fact of his reviewing the life of a naval officer from the outside, as it were, gives a new point of view and serves to bring into relief certain features which are apt to be overlooked by the professional naval writer. Although the battles of the Nile and Copenhagen receive adequate notice, the Battle of Trafalgar naturally takes the first place. Mr.

Thursfield's idea of the plan of attack at Trafalgar differs somewhat from those commonly accepted but after reading what he has to say the impression is deepened that at Trafalgar as in many other fights of that day the plan of battle as outlined before the fight was greatly modified to suit the exigencies of the hour This work will possess a particular interest for American readers, because so large a portion is devoted to an appreciative survey of the achievements of John Paul Jones. Mr Thursfield is the first English writer of prominence to remove the stigma which was attached to Jones's name by the calumnious writers of his day, and reveal him as the admirable character that he was. One of the most valuable chapters is that in which full justice is done to Admiral Duncan, the hero of Camperdown whose exploits and general professional ability seem never to have received adequate recognition until late in his career

SECOND APPENDIX TO THE SIXTH EDITION OF DANA'S SYSTEM OF MINERALOGY By Edward S Dana and William E. Ford. New York John Wiley & Sons, 1909 8vo., 114 pp. Price, $1 50

During the ten years of mineralogical investigation which this appendix covers, a large amount of material has been published An evidence of this is to be found in the two hundred new names which are given in the classified list in the introduction. About sixty of these new names on account of the completeness of their descriptions seem to have a warrant for their acceptance as new species. The other names are either of imperfectly described minerals or variety names of well recognized species. The descriptions of the new species included in this book are given concisely but completely It was found, however, impracticable to follow the plan adopted in the System and the First Appendix of recalculating all the angles and crystal constants of the new species. This has been done in a few cases, but in the majority of the descriptions the figures of the authors have been accepted without verification In the cases of some of the new species with complex crystals it has been impossible to give the complete lists of the forms identified upon them. The method followed has been to give the more common and prominent forms and to indicate the number of those not listed.

THE MAKING OF SPECIES. By Douglas Dewar, B A. and Frank Finn B.A. New York John Lane Company 1909 8vo 400 pp Price, $2 50, postage extra.

The authors aim in writing this book has been twofold In the first place they have attempted to place before the general public in simple language a true statement of the present position of biological science and in the second place they have endeavored to furnish the scientific men of the day with food for reflection As the British nation seems to be slowly but surely losing through its conservatism the commercial supremacy it had the good fortune to gain during the last century, so is it losing, through the unwillingness of any of her scientific men to keep abreast of the times, that scientific supremacy which she gained in the middle of the last century by the labors of Charles Darwin and Alfred Russell Wallace It is not among Englishmen but among Americans and Continentals that the world has to look for advanced scientific ideas. The authors fear that this book will come as a rude shock to many scientific men. What they attack is not Darwinism, but that which is erroneously called Neo Darwinism. Neo-Darwinism is a pathological growth on Darwinism which we fear can be removed only by a surgical operation The book is a beautifully printed one and will doubtless interest all naturalists.

THE ELEMENTARY PRINCIPLES OF INDUSTRIAL DRAWING. By George Jepson Oblong 12mo 28 pp, 11 plates.

The aim of this little book is to present the subject of industrial drawing, so that a student after he has become familiar with its contents, will have mastered all the essential principles as applied to mechanical and architectural drawing While the book presents all the principles of industrial drawing it is not a graded course of lessons, although if desired an elementary or more advanced course can be compiled from its contents. The author is an instructor in descriptive geometry machine drawing and shop work in the Massachusetts Normal Art School and was for many years master of the Evening Science School of the city of Boston The book appears to be an excellent one.

HENDRICKS'S COMMERCIAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS. New York Samuel E Hendricks Company 1909 Quarto, 1820 pp. Price $10

This is the eighteenth annual edition of Hendricks's Commercial Register of the United States. It is a complete and reliable annual index of industries, containing over 350,000 names and addresses of buyers and 33 000 business classifications Full lists are given of manufacturers and dealers in everything employed in the manufacture of material, machinery and apparatus used in these vast industries, from the raw material to the manufactured article and from the producer to the consumer. It is indispensable as a work of reference for the architect, engineer, contractor, manufacturer, jobber, retailer, exporter, purchasing agent, and for the railroad machine shop, foundry, mill, factory, mine, and plantation We have occasion to use several copies of this book, and it answers a vast number of our inquiries for manufacturers. It is a book which we can thoroughly commend.

Legal Notices

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending October 12, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Abdominal support J R Allred	936,752
Advertising device C A Myers	936,844
Aeroplane C W Cheney	936,303

FOUR INTERESTING LETTERS

PEARY

New York June 19th, 1908

Dear Sir —In regard to the watches furnished me by the Waltham Watch Co three years ago, the behavior of the meantime watches was particularly excellent

Watches carried by men in charge of different parties on the sledge journeys over the sea ice ran for weeks without any considerable variation from each other This feature was a very distinct comfort to me in making me feel sure of my observations when the drift of the ice had carried me far away from all dead reckonings

Most of these watches are now on Eagle Island Maine, where I am going the end of this week I will endeavor to get them on to you as soon as possible . . Very sincerely,

(Signed) R. E. Peary, U S. N

Mr. James W. Appleton.

WELLMAN

Washington D C Nov 27th 1899

American Waltham Watch Co Waltham Mass

Gentlemen —The nine watches made by you which were carried in the Wellman Polar Expedition proved entirely satisfactory Two of these were injured slightly by the Norwegian sailors in the early winter The remaining seven were used by me in ascertaining time and also positions of latitude and longitude Position of stars computed by the aid of these watches could be depended upon to the accuracy of a second Positions of longitude ascertained by Julius Payer twenty five years previously were verified

Extreme cold affected the movements but slightly and in no way injured them After returning to Norway but slight discrepancies were found upon comparing with Greenwich time

In my judgment these movements are thoroughly reliable for any use and in any clime being thoroughly compensated Yours truly

(Signed) Quirof Harlan
Physicist to Wellman Polar Expedition

The Shackleton Relief Expedition

British Antarctic Expedition 1907

S Y Nimrod
Lyttelton 27th March 1909

Messrs R W Cameron & Co Wellington

Sir Herewith I forward to you per Purser S S Maori the seven Waltham watches so generously loaned to my officers and self by your Company for our use in the Antarctic

Two of them unfortunately have been damaged One of them by an accident down a crevasse and the other during a sledge journey

My officers and I found the watches reliable under all conditions After a time we gained so much confidence in their rates that we had no hesitation in trusting to them when taking observations which required time-readings to seconds

On their behalf and my own I beg you will convey to your Company my thanks for the use of the watches I am Sir Yours faithfully

(Signed) Fred P Evans Lieut R N R
Officer Commanding

LEFFINGWELL

Mr. E. A. Marsh, Waltham Watch Company. The Quadrangle Club, Chicago, Dec 8th 08

Dear Sir —About three years ago your Company loaned me four of your watches for use on the Anglo-American Polar Expedition I received them from Robins, etc here and yesterday I returned three of them to the same people I wrote to you from the North last summer telling of the remarkable performances of these watches and my private Waltham during a two months sled trip over the ice They were compared with each other and chronometer corrected by observation nearly every day for a year and rates assigned for the ice trip Daily comparisons were made among the watches on the trip also, and with the chronometer after our return The field rates were found to be practically the same as those assigned from the rates during the several months previous to the field trip If it were not that all three watches came out the same, I should say that the obscure field rates were accidentally close to the calculated rates The performance of your watches is emphasized by the fact that Capt Mikkelsen had a hand-made pocket chronometer made to order in London at a cost of $250 00 On this trip this expensive time-piece varied so greatly from the mean of the other watches that it had to be disregarded after the first week The rates of your watches were changed but a fraction of a second, while the Captain s watch increased 35 seconds in its daily rate

I took the greatest care in getting the best possible performance from the watches I wore two myself and insisted that others took good care of them The watches were worn night and day next to the skin and every precaution taken to keep their temperature constant

Thank you very much for your kindness to us in loaning the watches Yours etc (Signed) E de K. Leffingwell

N. B.—In buying a Waltham Watch always ask your jeweler for one adjusted to temperature and position

How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT, 1615, A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr. Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT, 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

WELL DRILLING MACHINES

Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock. Mounted on wheels or on sills. With engines or horse powers. Strong, simple and durable. Any mechanic can operate them easily. Send for catalog.

WILLIAMS BROS., Ithaca, N. Y

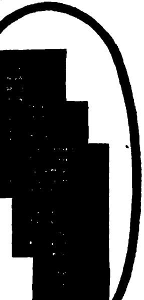
A Liberal Education in 3 Feet of Shelf Room

EX-PRESIDENT Eliot of Harvard, "first private citizen of America," says that the books a cultured person must read will go on a shelf 5 feet long.

But you will be glad to know that the REVIEW OF REVIEWS, after nine years of preparation, has just completed a work whose 44 exquisite volumes fill only three feet of bookshelf, and into which Hamilton Wright Mabie, Dr Henry van Dyke, Bliss Perry, George Iles and Tom Masson, as editors, have put a vastly more comprehensive, useful, readable and necessary private library than Ex President Eliot could possibly get into his five foot bookshelf

Ex President Eliot himself says of one section of this Masterpiece Library, which he saw before the whole was completed, "I know of no more complete and delightful selection than that which you offer the public in these charming volumes"

Other attempts at such a collection cost from one hundred to five hundred dollars. And there never has been one with a board of editors equal to that of the Masterpiece Library This one will cost you less than 50 cents a volume.



44 Volumes

The Masterpiece Library

In this set you have the best work of—Milton, Bacon, Swift, Goldsmith, Wordsworth, Tennyson, Scott, Thackeray, Dickens, Eliot, Browning, Stevenson, Barrie, Voltaire, Balzac, Daudet, de Maupassant, Zola, Goethe, Heine, Boccaccio, Hoffman, Turgenieff, Tolstoi, Franklin, Lincoln, Longfellow, Lowell, Hawthorne, Mark Twain, Howells,—and hundreds more of the world's greatest writers. Much of the material is copyrighted and much appears in English for the first time The editors contribute critical essays, which are "the last word" on their subjects.

There is not one selection in the books which you can afford not to read. You will read them—not once, but many times, because of their beauty, their sparkle and their intense interest.

44 Handsome Volumes

Each 4½ x 6 inches

10,000 Pages

Photogravure Frontispieces

400 Authors

American, English, French, German, Russian, Italian, Spanish

1200 Separate Selections

Prose, Poetry, Fiction, Humor, Autobiography

Less Than 50 Cents a Volume

Our large manufacturing establishment and tremendous clientele has enabled us to offer some very good bargains in the past—but never one like this. The introductory edition of the MASTERPIECE LIBRARY is now ready As long as it lasts, you can have a set for 50 cents down and $2.00 a month for 10 months. The coupon, with 50 cents, brings a complete set, *express prepaid* If you don't like it, send it back at our expense. If it is satisfactory you pay for it in small payments, and get FREE *The Little Masterpieces of Science.*

FREE The Little Masterpieces of Science This is in six volumes, bound to match the rest of the set. 30,000 sets have been sold at $4.50 a set. It contains the best work of Darwin, Huxley, John Fiske, Hall, Franklin and many others. In short, it does for Science what the Masterpiece Library does for Literature.

Thus adding these six volumes to the 38 volumes of the set you will have 44 volumes, in uniform binding—and they will make a splendid showing on your library shelves. Bear this in mind. Only the introductory edition goes at a bargain, with the Science volumes free. Don't wait until tomorrow to send the coupon, or you may miss the offer. Send it to-day You will be mighty glad of it later on.

Review of Reviews Co. 13 Astor Place New York

S.A. Send me the 44 volume Masterpiece Library [illegible] your special offer. [illegible] I will return it.

A SIMPLE METHOD OF TEACHING EXPERIMENTAL PHYSICS.

(Continued from page [illegible].)

taneously The needle traces an undulating line which cuts the base line in a series of points whose distances from the zero point are proportional to 1, 4, 9, 16, etc., that is, to the squares of the times. In this way the laws of falling bodies can be verified to within 1 per cent. This is a much closer approximation than can be obtained with Atwood's or Morin's apparatus, with which the beginning and end of the fall cannot be determined very accurately.

In other experiments the drum is driven by a cord, passing over the pulley and a grooved wheel 6 inches in diameter, attached to a simple driving clock, such as is used to turn a spit. With this arrangement the gradual diminution of the amplitude of successive oscillations of the pendulum, and the more rapid diminution brought about by attaching to the pendulum a paddle dipping into water, can be studied. The isochronism of small oscillations can be shown by giving the drum a uniform velocity of rotation, by means of the driving clock or of a weight which is stopped after it has fallen a certain distance. Then the base line and the undulations having been traced as before, the wave length, or distance between consecutive intersections of the two lines, is found to be constant, no matter what the amplitude or height of the wave may be, provided that it is small.

Chassagny's apparatus for compounding vibrations in the same plane (Fig 2) comprises two wheels mounted on parallel shafts. The first wheel is turned by a crank and drives the other by means of a belt. The ends of a fine violin string are attached to pegs inserted in the faces of the wheels at unequal distances from their centers, and the middle part of the violin string, which is kept taut by a spring, passes round a pulley, which turns freely on a vertical rod, attached rigidly to the horizontal axle of the nave of a bicycle wheel mounted in bearings. When the crank is turned both wheels revolve, and the horizontal displacement of the pulley, at any instant, is equal to the algebraic sum of the horizontal displacements of the two pegs. The movement of the pulley is followed accurately by a writing point which is attached to the other end of the bicycle nave. This point presses against a strip of smoked paper wrapped round a drum, which is turned by the engagement of a toothed wheel on its shaft with an endless screw on the crankshaft. The amplitudes of the two vibrations whose combined effect is sought are varied by varying the distances of the pegs from the axes of the two wheels, the phases are varied by setting one wheel, at the start, more or less in advance of the other by means of pointers attached to the wheels and fixed graduated circles behind them, the periods are varied by employing wheels of diameters proportional to the periods desired. For example, two wheels of nearly equal diameters give a graphical record of the phenomena of "beats."

Vibrations in mutually perpendicular planes are combined by means of an apparatus based on the same principle (Fig. 3) The resultant curves are traced on smoked glass so arranged before a lantern that the curves can be immediately projected on a screen and explained and studied at leisure, with a thoroughness that is not possible with the evanescent projections of Lissajous's figures made in the usual way, by reflecting a pencil of light from mirrors attached to tuning forks.

Chassagny's apparatus for the study of refraction consists of a glass globe supported by fixing its horizontal neck in a copper sleeve. If the neck is regarded as one pole of the globe, the opposite pole is indicated by an interruption in a copper meridian, and the equator is graduated in intervals of five degrees. Water is poured into a funnel attached to the upper side of the neck until its [illegible]

(Continued on page [illegible].)

Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A 1/4-H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS, AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid to explain the meaning of capillary elevation and depression to serve as a hydraulic tourniquet an aspirator and intermittent siphon; to demonstrate the ascent of liquids in exhaustive tubes to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1582.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1554.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil a pair of one-pint Leyden jars, and an inductance coil and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained with the help of diagrams, in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT, illustrated with diagrams, Scientific American Supplement 1606.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams, Scientific American Supplement 1604.

HOW TO MAKE A MAGIC LANTERN, Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplement 1494, 1599, and 1658.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1672.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE, Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522, and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1563, and 1566.

ANEROID BAROMETERS. Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1564.

A GREAT LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article published in Scientific American Supplement 1551.

Each number of the Scientific American Supplement costs 10 cents by mail.

Order from your newsdealer or from

MUNN & CO., Inc., 361 Broadway, New York

attains the level of the break in the meridian. The laws of refraction and total reflection can then be studied by directing luminous pencils toward the center of the globe, in the equatorial plane, and viewing them with the eye placed in the same plane.

In his electroscope (Fig. 4) Chassagny has made use of the fact that platinized glass is sufficiently transparent to allow objects to be seen clearly through it and yet reflects bright images of objects nearer the eye. A vertical and rigid strip of copper and a flexible strip of aluminium foil are suspended from a copper rod and inclosed in a case of which two opposite sides are of glass and the rest of metal. The rod carries a charging disk at its upper end and is insulated by passing through a block of paraffin, which rests on the top of the case. One of the glass sides is platinized, and outside it is placed a graduated quadrant which is seen by reflection, while the deflected strip of aluminium is seen through the glass.

Chassagny's galvanometer (Fig 5) is inclosed in a wooden case which is attached to the wall In a strong magnetic field, formed by placing the like poles of two horizontal horseshoe magnets almost in contact with each other, is suspended a coil of wire of electrolytic copper The intensity of the field is further increased by a soft iron cylinder, supported independently inside the coil A large mirror, attached to the coil, reflects the image of a lamp to a screen, where the movements of the spot of light can be followed by the whole class The galvanometer is provided with three shunts

In Chassagny's apparatus for the study of electromagnetic induction (Fig 6), a coil of wire is attached with its plane vertical, to one end of a lever which can turn round a horizontal axis, and is balanced by a counterpoise on the other end A vertical horseshoe magnet, with its poles directed upward, is placed so that the coil can be brought between the poles or raised above them, by turning the lever on its axis The positive and negative currents produced by these movements are indicated by a galvanometer connected with the coil An alternating current is produced by allowing the lever to oscillate freely Other experiments in induction may be made by sending through the coil a current from a battery

M Chassagny has devised a number of other ingenious instruments, including a very practical rheostat, a eudiometer, a baroscope, etc.

◆

THE LATEST SUBMARINES OF THE UNITED STATES NAVY

(*Continued from page 206*)

merged condition, certain valves in the interior of the boat are opened This allows the water from the sea to run into great tanks built within the boat and thus virtually sink her These tanks are closely gaged, so that just the required amount of water is taken in Under normal conditions, when the boat is at rest with the ballast tanks filled, she will have a few hundred pounds reserve buoyancy, which is represented by the top of her conning tower protruding above the water If desired, this buoyancy may be entirely destroyed by admitting a small additional amount of water, equal in volume to the volume of that part of the conning tower above water While in the submerged condition, all communication with the outside atmosphere is necessarily cut off The crew, usually about fifteen men, then breathes the air contained in the body of the boat. The amount of air originally contained within the hull is sufficient to support life with comfort for at least twenty-four hours But, in addition to the air thus contained, the boat carries a large supply of compressed air in steel flasks, which, if used for breathing purposes, would be sufficient for a number of days.

After having brought the boat to the submerged condition, in the manner

(Continued on page [illegible].)

KOH-I-NOOR Pencils are made in 17 different degrees of hardness and softness—6B to 9H.

The standard of Pencil Quality throughout the world. Each degree, and each pencil in each degree, is always the same. 10c each, $1 a doz. If your stationer will not supply you—write to us.

L. & C. HARDTMUTH, Est. 1790, 34 E. 23d St , New York

THE MIDDLE WEST NUMBER

To most Americans the Mississippi Valley and the rich country that spreads outward from either of its shores is farmland—a country which may well be regarded not only as the granary of the United States, but of a large portion of the world as well.

The Middle West is more than this. It is a country of wonderful engineering development and achievement, wonderful because of the enormous scale on which its industrial works have been planned.

On December 11th, 1909, the SCIENTIFIC AMERICAN will issue a number devoted entirely to this Middle West region, a number which will set forth broadly and luridly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West, in part at least, into a manufacturing territory

With that object in view the Middle West Number will publish articles on the following subjects:

I. THE CHICAGO AND GULF WATERWAY —An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II. CHICAGO AS A RAILROAD CENTER.—Very few Americans realise that Chicago is the greatest railroad center in the world and that it may be likened to a great hub from which radiate the spokes of American transportation

III. THE WONDERFUL GRAIN TRADE OF CHICAGO.—Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured. The conveying and handling of that huge amount of grain has necessitated the erecting and constructing of ingenious machinery and elevators

IV SHIPPING ON THE GREAT LAKES.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation Ships of 10 000 and 12,000 tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world

V THE HANDLING AND SHIPMENT OF IRON ORE.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. FREIGHTING ON THE MISSISSIPPI.—The Mississippi is the great natural waterway of the middle West It places the cities along its banks in direct water-communication with every port in the world That is why freighting on the Mississippi is a more important industry than most of us may realise

VII. THE STEEL INDUSTRY —Although the steel industry is still centered in Pennsylvania the scene of its activity is gradually shifting One of the greatest steel plants in the world is that which has been built at Gary It is safe to say that nowhere else in the world will be found a plant so remarkably equipped and so efficient

VIII. THE FREIGHT SUBWAY SYSTEM OF CHICAGO Chicago can boast of a rational system of handling freight by means of subways. Freight is carried from the railway car directly to the warehouse by means of tunnels aggregating sixty miles in length

IX. THE WATER SUPPLY OF CHICAGO —Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake

X. RECLAIMING ARID LANDS.—The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered.

XI. HARVESTING THE GRAIN OF THE MIDDLE WEST —Farms that cover not acres but square miles, crops that aggregate not simply bushels but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated.

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN. It will be lavishly illustrated. It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

BUSINESS OPPORTUNITIES

WILL FURNISH capital for promoting good patent, franchise for public utility or other good enterprise. Must come well recommended. Address P. L. Gallagher, Prudential Building, Newark, N. J.

Inquiry No. [illegible].—Wanted to buy nickeloid for buttons.

MANUFACTURERS.—Let me tell you what a fortune I have for you. I have a new patent manure spreader which I will sell at a reasonable cash price to any business man or to factories. It is both simple and practical. It is built in [illegible]-inch side and works to perfection. If interested write personally to G. G. Halsman, Kanawa, Iowa.

Inquiry No. [illegible].—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

MANUFACTURERS, CAPITALISTS. I will sell outright or manufacture on royalty a most valuable invention. For full particulars address M. R. Schultz, Southampton, N. Y.

A RARE OPPORTUNITY presents itself for a high class salesman to handle an article of utility needed on every street, in every home and store as well as halls and churches. Substantial commissions or straight purchase plan. Standard Chicago, 9 W. Michigan St., Chicago.

Inquiry No. [illegible].—For the address of the Windsor Mfg. Co. manufacturers of waterproof collars and cuffs.

PATENTS FOR SALE

FOR SALE.—Valuable hoop-shaving patent, improves quality and greatly reduces cost of manufacture. For further information and particulars, inquire Room 1702, 11 Pine Street, New York.

Inquiry No. [illegible].—Wanted the address of Worthington Boiler Co.

FOR SALE. Patent No. [illegible]. Door knob to adjust to doors of various thicknesses. No small screws to loosen and drop out. Can be made cheap. Address J. T. Henderson, Box 24, Niagara Falls, Canada.

Inquiry No. [illegible].—Wanted the address of the [illegible] Motor Co.

FOR SALE. Self spinning top. Mechanism all inside; will spin five minutes with one winding. Will sell outright or on royalty. U. S. Patent [illegible] August 17, 1909. T. N. Reed, Itasca, Tex.

Inquiry No. [illegible].—Wanted the manufacturers of the Van Winkle, Woods & Sons, and the Weber power motors.

FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all pipe threads, 4 to 40 in. Price only $[illegible]. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. [illegible].—For information regarding shoes not made of leather but similar to the same and are as durable.

BOOK AND STATIONERY BUSINESS established 20 years, location in thriving city of [illegible], splendid field and well developed neighborhood, western Minnesota; must be sold because of ill health. Will sacrifice heavy discount on actual value. A competence for the right man and less than $2,000 will swing it. H. L. Wheelock, Fergus Falls, Minnesota.

Inquiry No. [illegible].—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE.—Brand new aeronautic motor 30 H. P. A 4-cylinder air-cooled, 2-cycle engine weighing less than 4 lbs. per H. P. Built by one of America's pioneer boat motor constructors. Will sell cheap to quick purchaser. Address H. A. Powell, Stratford, Conn.

HELP WANTED

WANTED.—A practical and experienced man, thoroughly conversant with up-to-date stock and cost systems for iron and brass manufacturing plants. A permanent and lucrative position for a good man. Apply by letter, stating experience and qualifications, to "System," Box 773, New York.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

WANTED BY NOVEMBER 1st.—Superintendent for wood working machinery plant, must have good education and be well up in machine shop practice and designing. Applicants will please state age, experience and salary required. Hespeler Machinery Co., Limited, Hespeler, Ont., Canada.

PARTNERS WANTED.

WANTED.—Partner with sufficient capital or a business firm or corporation to manufacture article under Patent No. [illegible] on a royalty basis or for sale. Goods are staple and cheaply made. Partner, Box 773, N. Y.

Inquiry No. 9010.—Wanted to buy a "Rector Help-a-Phone."

MISCELLANEOUS

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days' free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., [illegible] Barclay Block, Denver, Colo.

Inquiry No. 9012.—Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

Inquiry No. 9018.—Wanted, the address of parties manufacturing gold-plated pens for use in cheap fountain pens.

Inquiry No. 9022.—Wanted to buy a light, small motor, not exceeding three pounds in weight, including everything in going order.

Inquiry No. [illegible].—Wanted, to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

Inquiry No. [illegible].—Wanted, address of rubber manufacturers in Germany.

Inquiry No. [illegible].—Wanted, address of parties who make "Invar" or other metals having a low coefficient of expansion.

Inquiry No. [illegible].—Wanted, the address of manufacturers of small wooden articles.

Inquiry No. [illegible].—Wanted, to buy a washing machine that is run by a coil spring motor.

Inquiry No. [illegible].—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. [illegible].—Wanted, the address of firms manufacturing a wood fiber bottle and case made from same material.

Inquiry No. [illegible].—Wanted the address of parties who supply carriage and wagon makers with white gum wood blocks for making hubs for vehicle wheels.

Inquiry No. [illegible].—Wanted, to buy machinery, etc., to install a plant for manufacturing condensed, malted and evaporated milk.

Inquiry No. [illegible].—For manufacturers of machinery that could reduce stumps to kindling wood.

above described, powerful electric motors are started by throwing in a switch. These motors derive their energy from storage batteries contained in the boat, and drive the propellers. The same storage batteries furnish current for numerous auxiliary motors used for pumping, steering, handling torpedoes, etc.

The motion of the boat when under way is controlled by two sets of rudders, one of these sets, known as the vertical rudders, directs the boat's course to port or starboard just as does the rudder of an ordinary ship. In addition, there are provided horizontal rudders, which serve to control the motion of the boat in a horizontal plane; that is to say, the depth at which she runs is regulated by these rudders. For steering in the horizontal plane, instruments are provided so that the boat may be navigated with the same degree of accuracy as boats on the surface. The first of these instruments is known as a periscope. This consists of a vertical tube which extends from above the surface of the water to a few feet within the submarine. At the top of the tube is an object glass, at the bottom an eye-piece. Two reflecting mirrors, one at the top, the other at the bottom of the vertical tube, cause the image to be transferred from the object glass to the eye-piece. The operator can turn the periscope so as to sweep the whole horizon. To the writer, who recently made a five-hour trip in one of our latest boats, the view was as clear as though he were at the surface looking through an ordinary field glass. Hence when running submerged with the top of the periscope just out of the water, the navigator can see with perfect ease surrounding objects. If for any reason it should be desired to run at a still greater depth, compasses are provided by which the course may be steered with accuracy. For steering submerged, in the vertical plane, instruments are provided which in a way take the place of the compass. One of these is a large pressure gage, which indicates the depth at which the boat is running. Another is a form of spirit level, which indicates the inclination of her axis. By the use of this, the man controlling the horizontal rudder is able to run at a perfectly even depth. While in the submerged condition the boat is of course amply illuminated by electric lights. There are no ports or windows in the boat and so far as sensations are concerned, one is unable to determine whether he is running on the surface or submerged.

The arm of the submarine is the automobile torpedo. A number of these may be carried. They are discharged through torpedo tubes located in the bow of the boat. Any modern type of automobile torpedo may be used. In view of the fact that the submarine is enabled to approach unseen to within a few yards, if desired, of the most powerful battleship a long-range torpedo is not required. For this reason the weight devoted to motive power in the ordinary torpedo may be largely used to increase the destructive power, so that the proper arm for the submarine would be far more powerful and destructive than the ordinary automobile torpedo.

While the project of the submarine is comparatively old, it has so happened that but few of them have been used in real war. The first case on record is that of a little hand-power submarine boat built by David Bushnell in 1776. Having obtained permission from the American general in command to use this submarine against the English fleet anchored north of Staten Island, he instructed a sergeant named Ezra Lee in its use. After several attempts, Lee made an attack on one of the ships. His purpose was to fix a torpedo to her side, then go away and allow it to explode, thus destroying the ship. Unfortunately, the ship was sheathed with copper, and he was unable to attach his mine. Lee then drifted away from the ship, having abandoned his mine, which, after drifting about for an hour, exploded, throw-

(Concluded on page 307.)

Important Books

Hydraulic Engineering

By GARDNER D. HISCOX, M.E.

PRICE $4.00

A practical treatise of 316 pages and containing [illegible] illustrations on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horsepower of falling water; turbine and impact water-wheels; [illegible]

A comprehensive [illegible] and for this reason should have a place in the working library of every engineer.

Electric Wiring, Diagrams and Switchboards

By NEWTON HARRISON, E.E.

272 pages. 105 illustrations. Price $1.50

This work is a thoroughly practical treatise on Electric Wiring in all its branches, beginning with the simple circuit and working up to the practical every-day problems, all being presented in a simple and intelligent manner. Only arithmetic and simple algebraic formulas are used in the calculations and explanations. Originality is shown by the author in the method of presentation of the matter, the liberal use of tables helping to a clear understanding of the subject.

While more than half the work is devoted to wiring and related subjects, there is a good deal of other information that will be found generally useful. There is a chapter on incandescent lamps, which includes tabulated data on this topic. Switchboards of the various types, their design, etc., are considered in three chapters, and the accompanying diagrams are clearly executed and easily understood. The remaining chapters briefly review the nature and characteristics of alternating currents and their practical application is described. It is in every respect a handy, well-written, instructive, comprehensive volume on wiring for the wireman, foreman, contractor or electrician.

Practical Steam & Hot Water Heating and Ventilation

By ALFRED G. KING

PRICE $3.00

402 Pages. Containing 304 detailed illustrations. The larger part of them having been made from original diagrams, specially drawn for the book.

An Original and Exhaustive Treatise, Prepared for the Use of All Engaged in the Business of Steam, Hot Water Heating and Ventilation.

The Standard and latest book published. Tells how to get heating contracts, how to install heating and ventilating apparatus. Describes all of the principal systems of steam, hot water, vacuum, vapor and vacuum-vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation; fan or blower system of heating and ventilation; rules and data for estimating radiation and cost, and such other tables and information as make it an indispensable work for heating contractors, journeymen steam fitters, steam fitters' apprentices, architects and builders, etc. This work represents the best practice of the present day and is exhaustive in text, diagrams and illustrations. Valuable data and tables used for estimating, installing and testing of steam and hot water and ventilating apparatus are given.

Telephone Construction, Installation, Wiring, Operation and Maintenance.

By W. H. RADCLIFFE, E.E., and H. C. CUSHING, JR., E.E.

PRICE, $1.00

A Practical Book of 180 Pages and Containing 125 Illustrations, Intended for Electricians, Wiremen, Engineers, Contractors, Architects and Others Interested in the Installation of Telephone Exchanges in Accordance with Standard Practice.

This book gives the principles of construction and operation of both the Bell and Independent instruments; approved methods of installing and wiring them; the means of protecting them from lightning and abnormal currents; their connection together for operation as series or bridging stations; and rules for their inspection and maintenance. Line wiring and the wiring and operation of special telephone systems are also treated. [illegible]

MUNN & CO., Inc., Publishers, 361 Broadway, New York

had up a great volume of water, and thus warning the English of the great danger they had escaped.

Another case on record is that of the Confederate submarine "David," which, during the blockade of Charleston in the civil war, was manned by volunteers, and by hand power was propelled out to the U S. S. "Housatonic," which she destroyed by the explosion of a mine in contact with her hull.

During the Spanish-American war the modern submarine had not made its appearance. During the Russian-Japanese war both sides ordered boats, but the war was finished before these vessels became available. At present all the leading naval powers are acquiring submarines in large numbers, so that during the next war we may expect to see them figure largely in the various operations.

In the trip in a submarine above referred to the Editor was impressed with the smoothness and accuracy with which the submarine went through her submerged evolutions. The movements, quick response, etc., of the boat were such as to inspire complete confidence in her stability and general efficiency

There can be no question that the submarine has at last "come into its own" Among the captains of the battleships and the line officers in general at Provincetown, there was noticeable a growing respect for these craft, due to the varied and accurate work which the flotilla had accomplished during the summer maneuvers. There has been a steady but slow growth in the speed of the submarine. Its control is now perfect, and its radius of action is being rapidly increased Our largest boats have a radius of about one thousand miles and two are under construction on the Pacific coast which will have a cruising radius of about three thousand miles. This means that the submarine is taking on full seagoing qualities It must no longer be regarded as restricted to seacoast operation The time is not far distant when an admiral searching for the enemy upon the high seas may include a submarine flotilla in his fleet. The profound significance of this fact upon strategy and tactics will be appreciated by every naval expert.

◆

In his study of living beings, the physiologist has one guiding principle which plays but little part in the sciences of the chemist and physicist, namely, the principle of adaptation. Adaptation or purposiveness is the leading characteristic of every one of the functions to which we devote in our text-books the chapters dealing with assimilation respiration, movement, growth, reproduction, and even death itself. Spencer has defined life as "the continuous adjustment of internal relations to external relations." Every phase of activity in a living being is a sequence of some antecedent change in its environment, and is so adapted to this change as to tend to its neutralization and so to the survival of the organism. This is what is meant by adaptation. It will be seen that not only does it involve the teleological conception that every normal activity must be for the good of the organism, but also that it must apply to all the relations of living beings. It must therefore be the guiding principle, not only in physiology, with its special pre-occupation with the internal relations of the parts of the organism, but also in the other branches of biology, which treat of the relations of the living animal to its environment and of the factors which determine its survival in the struggle for existence. Adaptation therefore must be the deciding factor in the origin of species and in the succession of the different forms of life upon this earth.

◆

In consequence of the part played by the gas-lighting equipments of the trains involved in some recent accidents, states a contemporary, the Prussian railway authorities have decided to convert all their sleeping cars now fitted for gas lighting (some 150 cars) for electric lighting.

Jaeger

The ideal underwear for outdoor recreation. No sportsman, hunter, golfer, yachtsman or motorist should be without it.

SPARK COILS
Their Construction Simply Explained

Scientific American Supplement 160 describes the making of a 1½-inch spark coil and condenser

Scientific American Supplement 1514 tells you how to make a coil for gas-engine ignition.

Scientific American Supplement 1522 explains fully the construction of a jump-spark coil and condenser for gas-engine ignition.

Scientific American Supplement 1124 describes the construction of a 6-inch spark coil.

Scientific American Supplement 1087 gives a full account of the making of an alternating current coil giving a 5-inch spark.

Scientific American Supplement 1527 describes a 4-inch spark coil and condenser.

Scientific American Supplement 1402 gives data for the construction of coils of a definite length of spark.

The above-mentioned set of seven papers will be supplied for 70 cents.

Any single copy will be mailed for 10 cts.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

A Failure at Fifty

Out of a job at fifty—is the fate of the untrained man

Business requires not only natural ability but special training

The Trained Man Can Defy Old Age

The American School of Correspondence can fit you for congenial well paid positions in your early years, and make your services valuable in your old age Training only can compensate for the energy of youth

For thirteen years the School's *Engineering Courses* have set the standard for thoroughness and practicalness in correspondence instruction. The School has trained thousands of men for the technical professions, or has advanced them to higher positions. To-day these courses represent the highest development of correspondence teaching

The Courses in Commerce, Accountancy and Business Administration

set the same high standard in the commercial world They prepare for the best-paid business positions, they are prepared by practical business men who have "made good" by practicing what they teach they are planned to meet the needs of both the young man who is just starting in and the older man who has almost "arrived."

Get your training now while you have the time and energy for study Mail the coupon to-day

Do You Gamble?

Some people spend their money and energy housing a splendid crop of grain cotton or tobacco, and then gamble with Providence on its safety until sold Do you?

Other people put the savings of years into a home and then rely on their *luck* to avoid the thousand and one chances of fire Do you?

Still other people invest their entire assets in a store or a factory and then wholly or in part insure themselves, thinking that they can carry the risk as well as the insurance company Do you?

The average man has most of his property in one place To carry his own insurance is to depend upon chance i e to gamble, with ruin as the penalty for losing The business of the insurance company is founded on the law of averages. It can be safely conducted but only when its stability is based on the experience of tens of thousands of risks widely distributed over a continental area

The Hartford Fire Insurance Company offers unsurpassed indemnity Its business is distributed among more than fifteen thousand cities, towns and villages throughout the United States and Canada. During 99 years it has paid every just claim—more than $125,000,000 in all Its policies are safeguarded by ample resources and an honorable record

The "Hartford" insures all classes of property It also serves property owners by telling them how to guard against the dangers of fire It has published a book on the subject, "Fire Prevention and Fire Insurance," with separate chapters for householders, merchants and manufacturers that will be sent free to those who apply for it

Insure in the "Hartford"

To secure a "Hartford" Policy or the book referred to above, apply to the

SLAG A CAUSE OF BROKEN RAILS

The scientific investigation of the cause of broken rails has a strong claim on popular interest and this for the reasons that we all are more or less frequent travelers by rail and that the breakage of rails is one of the most fruitful causes of serious railroad accidents The agitation of three years ago which followed upon the publication by the State authorities of statistics showing an alarming increase in the number of broken rails has been productive of excellent results It has served to bring together the rail manufacturer and the railroad engineer in a joint endeavor to determine more exactly the causes of rail failure and devise improvements in the methods of manufacture which will give a thoroughly reliable rail without entailing an undue amount of extra cost in the making

During these intervening three years a most exhaustive chemical and mechanical investigation of the subject has been made and many hitherto obscure and little-understood facts have been brought to light regarding the mechanical condition and chemical composition of faulty rails the causes which have produced these conditions and the best methods of casting and working to produce a rail which will stand up under its work without betraying that alarming liability to sudden fracture which has caused so much loss of life and property during the past few years.

One of the latest papers on the subject was that presented by Messrs Fay and Wint at the annual meeting of the American Society for Testing Materials in which attention was drawn to the frequency with which rail breakages may be traced to the presence of slag The investigation by these gentlemen of rails that had broken in the head shows the presence of excessive slag a segregation of slag concentric with the rail section remnants of slag in the large split portion of the head, and slag in those areas where flow of metal has occurred or where microscopic cracks have developed While it is impossible from the evidence so obtained to state definitely the exact cause of fracture, it is highly probable that it is due to imperfectly welded blowholes or pipes The investigation showed that at the point of fracture there is always to be found a large amount of slag that cracks invariably begin in and follow from one slag area to another and that cracks within the body of the metal produced by shrinkage strains will follow along the slag areas Thomas Andrews, in his paper entitled Microscopic Internal Flaws Inducing Fracture in Steel considers it to be a most significant fact that in the various material he examined, almost without exception there was a considerable slag area, in or near the fractured surface, and he says that the internal microscopic flaws which are almost invariably present in steel forgings constitute a chief source of initial weakness in axles rails shafts heavy guns etc.

The hard spots which have been observed in broken rails are apparently due either to imperfect mixing and solution of the ferro-manganese or to the hardening of the surface of the metal due to slipping of the driving wheels or to segregation in steel alloys. The first and second causes are not common, but the third, which is due to the imperfect melting of the alloy, is more serious. An examination of several nickel steel rails which had broken in service showed streaks of very hard, medium hard, and soft metal and it is the belief of the authors of the paper that this lack of uniformity is due to segregation of the nickel during the cooling of the ingot It is suggested that the various defects above mentioned could be remedied, first, by using a specification asking for lower sulphur, secondly, by allowing more time between the addition of ferro-manganese to the hot metal in the ladle and the pouring of the metal into the ingot mold, and thirdly, by pouring the metal from the bottom of the ladle Finally, although Messrs. Fay and Wint believe that electric refining will remove many of the difficulties attendant upon the present method, it must not be assumed that this would prove to be a panacea, since without competent control bad steel can be produced just as easily in an electric furnace as by any other method

OUR VANISHING TIMBER SUPPLY

When the adventurous navigators of three or four centuries ago skirted the coasts and entered the bays and rivers of this country, they were impressed with the extent and variety of the forests which everywhere spread their rich mantle over the country And well they might be, for the original forests of the United States exceeded in the quantity and variety of their timber the forests of any other region of similar size on the globe Nature was lavish when she laid out and planted the five great forests of this country, and lavish she was when she planned its noble watercourses, smoothed out the vast arable lands of its prairies and wide-spreading valleys, and stored below the surface its priceless wealth of iron ore, coal, oil and precious minerals Where Nature had been so prodigal of her supplies it was perhaps inevitable that man should become equally prodigal in their use, and no doubt the extravagance and wastefulness which have become a national characteristic, are due largely to natural environment

Of all the natural resources of the country, our forests have been one of the worst, if not the worst sufferers from extravagance, and this is proved by the simple fact that we use (or waste) ten times as much timber per capita as they do in France, and are, consequently cutting our forests three times as fast as they are growing The original forests of the United States included five great forest types. The Northern forest reached from Maine through New England, New York and Pennsylvania, to Georgia, and through central and northern Michigan and Wisconsin to Minnesota, and covered about 150 000,000 acres mainly of cone-bearing trees The Southern forest commenced in New Jersey, and reached from the coast far inland through Virginia the Carolinas Georgia, Florida Alabama, Mississippi and Louisiana and portions of Texas, Oklahoma, and Arkansas This is the great belt of the yellow pine Its total original area was about 320 000 000 acres. The Central forest, which extended between the northern and southern forests from the Atlantic coast to the western prairies is the great source of our supply of hard woods. Originally it included not less than 280,000 000 acres. Then to the westward was the Rocky Mountain forest, extending from Montana and Idaho to New Mexico. Here on the high plateaus and mountain slopes is a growth of coniferous trees, including western yellow pine, Douglas fir larch, spruce and cedar Its original extent was at least 110,000,000 acres. Lastly, and the grandest of all, was the Pacific coast forest, extending through Washington, Oregon, and California, whose original area of at least 90,000 000 acres was covered with the most majestic growth of coniferous trees in the world

Much has been said and written of late about the destruction of our forests, and one of the latest and most illuminating pamphlets on the subject is that by R S Kellogg, Assistant Forester in the Forest Service of the Department of Agriculture who tells us that, whereas, at a conservative estimate these five great forests of the United States covered originally 850,000,000 acres and contained 5,200 billion feet of timber, at the present time their total area has been reduced to 550,000 000 acres, containing less than one-half as much standing timber than they did in their virgin state.

The total yearly drain upon our forests, not counting losses from fire, storms, and insects, is estimated to be about 20,000,000,000 cubic feet. Of our present forest area of 550,000,000 acres, 200,000,000 acres are roughly estimated to consist of mature forests, in which the annual growth is balanced by death and decay, and 250,000,000 acres consist of timber partially cut or burned over, on which with reasonable care there is sufficient young growth to produce ultimately a merchantable, but not a full crop of timber The remaining 100,000,000 acres consists of forests so completely cut out and burned, that there is not sufficient young growth to produce another crop of much value According to this estimate, the annual growth of all our forests is not over twelve cubic feet per acre, or a total of less than seven billion cubic feet. Since we cut yearly some twenty billion cubic feet over and above what is lost by fire and other natural causes, it follows that we are cutting out our forests three times as fast as they are grown. Just how unreasonably extravagant this country has been in using up its timber supply, is shown by comparison with the conduct of Germany and France. In Germany 37 cubic feet of timber per capita are taken annually from her forests, France is able to get along with but 25 cubic feet; while in this country the consumption is 250 cubic feet per capita. Germany, furthermore, has applied her scientific methods with such good effect, that her state forests are producing to-day an annual average of 48 cubic feet of wood per acre.

It is considered that the demand for more farm land may eventually lead to a further encroachment to the extent of 100,000,000 acres upon our present forests, reducing the total to 450,000,000 acres. The Forest Service considers, however, that it would be entirely possible, if the forest land is improved and the timber economically cut and completely utilized, to produce on the remaining 450,000,000 acres sufficient wood for a population much greater than we now have in the United States.

DEATH OF PROF LOMBROSO

Cesare Lombroso, certainly the most widely known if not the most authoritative criminologist of our day, died on October 19th 1909 at Turin, Italy, at the age of sixty-four If Lombroso had never written anything else than his "Criminal Man," his name would be handed down in the annals of psychology Even though in his later years he was given, without careful investigation, to rather hastily fitting into his theory any newspaper story or fact that might have met his eye, it must be stated that his contributions to criminal anthropology are valuable and lasting. His theory that criminals must be regarded as mentally diseased persons although not yet legally accepted by society as a whole nevertheless finds favor with a large number of psychologists No doubt his system of criminology is not so far developed that we are justified in abolishing prisons and treating criminals in insane asylums as Lombroso advocated but at least it tends toward a scientific solution of the problems presented by crime and its punishment

It was while he held the post of army surgeon that Lombroso's attention was first drawn to malformations of the skull. An executed murderer's cranium was so markedly malformed, that he was induced to make an investigation to ascertain whether or not the man's crime might not have been occasioned by his cranial defects. The rest of Lombroso's life was spent in piling facts upon that original fact As a lecturer on psychology at the University of Pavia he later had abundant opportunity for studying inmates of the insane asylum there, and was impressed with the connection between nutrition and sanity As a result of that study, he showed that a poor quality of maize was responsible for much of the pelagra from which Italian peasants were suffering After a hard campaign he succeeded in inducing the authorities to take measures to reduce the disease. Lombroso's researches were extended also to the study of epilepsy and genius. His theory that genius was a form of insanity was widely heralded and attracted not a little comment both hostile and favorable.

Recently Lombroso devoted much time to the study of spiritistic phenomena. He made an elaborate study of Eusapia Paladino and was won over by her to a partial belief in the physical manifestation of spiritualism, yet he was never quite willing to accept spiritualism in the sense of preservation of personal identity after death

COUNT DE LAMBERT'S FLIGHT OVER THE EIFFEL TOWER.

The most sensational flight ever made in an aeroplane was that accomplished by Count de Lambert with his Wright biplane on October 18th, when he flew from the aerodrome at Juvisy, where an aviation meeting was in progress, to Paris and back, covering a distance of about 30 miles in 49 minutes and 39 seconds. After making two circuits of the aerodrome, Count de Lambert headed for Paris, and, continually rising, soon disappeared from view He flew over Paris at a great elevation, and by the time the Eiffel Tower was reached, he had risen sufficiently to clear it nicely He passed directly over the tower, which is 984 feet in height, turned his machine around, and headed back for Juvisy. He arrived and landed safely, and was greeted by Orville Wright, who had just arrived from Berlin after making a special flight for Emperor William—the first aeroplane flight the German Emperor had ever witnessed—a few days before. While in Germany, Orville Wright also made a record height flight, in which he reached an elevation of about 1,600 feet, as near as he could estimate. Count de Lambert's height was visibly demonstrated by his passing over the Eiffel Tower At a height of 1,000 feet the principal sensation he experienced was that his aeroplane appeared to be scarcely moving. The time, he said, seemed interminable ere he finally reached his starting point. His average speed was about 37 miles an hour.

ENGINEERING

Work on the last section of the Jungfrau railway has progressed so well during the recent summer, that it will probably be opened next year from Eismeer to Jungfrau Joch. A station at the former place has been hewn out of the solid rock at an altitude of 3 153 meters, capable of accommodating 200 persons.

Buenos Ayres, the name of which suggests palm trees and sunshine and the transaction of business with sub-tropical leisurely haste, is getting sufficiently busy to demand subways. A bill is pending in the Argentine Legislature to authorize the construction of underground electric railways operating in connection with existing surface lines.

The Wolseley Motor Car Company, leading makers of "all-British" automobiles, are giving special attention to aeroplane engines and have delivered several V-type 50-horse-power machines to intending aviators. These motors, although they weigh only 300 pounds, are claimed to be capable of delivering as high as 75 horse-power One of them was recently installed in a new Voisin biplane.

The Austrian government appears to be divided upon the "Dreadnought" question, the proposed expenditure upon naval construction for next year having been reduced by $5,000 000 A torpedo cruiser named "Admiral Spaun will be launched about the end of this month, the first ship of the Austrian navy to be equipped with Parsons turbines, with an estimated speed of 26 knots.

It appears that the Siberian railroad is beginning to show the inevitable results of the haste and cheapness with which it was constructed The sharp curves and heavy grading have put serious limitations upon traffic, and for great distances the reconstruction will involve an entirely new location The road is to be changed from single to double track and the officials are greatly regretting that the large and costly bridges were built to accommodate one track only On the level plains the double tracking will not be such a serious matter but in the heavy cuts of the mountain division, and where the steel bridges over the wide rivers will have to be rebuilt, the cost will be very high

The rapid advance of aviation to the dignity of a science is indicated by the fact that the University of London has arranged for a special course on aeronautics to be conducted by Mr A. P Thurston one of Sir Hiram Maxim's engineers It will consist of a series of lectures followed by drawing office practice in the design and construction of aeroplanes The syllabus of the lectures is as follows (1) The normal and inclined plane (2) Stream line surfaces, center of pressure and resistance of bodies (3) The propeller and helicopter (4) Calculations applied to a flying machine. (5) The biplane. (6) The monoplane (7) Aeronautical engines (8) Automatic stability and control (9) Dirigible balloons

During the past season the old, deep-keel, narrow beam English cutter 'Bloodhound' has been scoring some remarkable wins in races against cutters of the most modern design. Commenting on her performances, the Yachtsman of London says that opinion has been expressed that many present-day designers do not know their business and adds 'Speaking for ourselves, we say without hesitation that they do not It is not by any means our purpose to eulogize the performances of the Bloodhound' unduly, but we repeat that there is something wonderful in the fact that a yacht so antiquated in shape was able to beat two modern cruisers of fifty per cent over her tonnage" Of course, the feat was performed in strong winds and under reduced canvas. It is in light weather that the modern yacht is so greatly the superior to the older craft.

Tests have recently been concluded by Messrs Burstall and Monkhouse, of London, of a portable combined boiler and engine, the economy and efficiency of which are so remarkable that we shall hope to describe the tests more in detail either in the SCIENTIFIC AMERICAN or SUPPLEMENT in the near future, limitations of space preventing their adequate discussion at present. The engine is a so-called "locomobile," built by the Wolf Engineering Works of Magdeburg Buckau, but it must not be confounded with the automobile of that name, as it is not strictly an automobile engine. It consists of a locomotive type boiler, from which the steam is conducted through a superheater in the smokebox directly to the high-pressure cylinder of the engine, which is tandem compound and mounted directly on the boiler under the same jacket, so that the cylinders are surrounded by the flue gases. Such is the heat economy effected by this arrangement, that this commercially constructed "stock" engine and boiler, adaptable to threshing, plowing, sawing, or any of the ordinary work of a portable engine, develops 1 brake horsepower with 1.66 pound of coal and 8.81 pounds of water The efficiency is very little reduced by running the engine with 25 per cent above its economical load, or 25 per cent below.

ELECTRICITY

A contract has just been given by the Brazilian government to a French telegraph company to erect a wireless telegraph station on a small island 200 miles off the coast of Rio Grande do Norte the easternmost point of South America. The island is 400 miles from Pernambuco The station will have an operating radius of 1,000 miles. It will be connected by an auxiliary station at Pernambuco with the Brazilian telegraph system.

The city of Baltimore has adopted an ordinance which requires the testing of every electric meter by the Department of Lamps and Lighting, before the meter may be installed A charge of ten cents is made for each inspection Any consumer who is suspicious of his meter may have it examined by the department. A charge of $1 is made for this service, which is borne by the consumer if the meter is registering properly or by the company if the meter is found to be at fault.

The recent announcement of the British Welsbach Company that it has entered the electrical field and is manufacturing metallic-filament electric lamps, has caused quite a stir in England. Many look upon this news as a blow to the gas business Welsbach mantles have heretofore made it possible for gas to compete with electricity as an illuminant but the fact that the Welsbach Company is taking up the manufacture of electric lamps would seem to indicate that the gas mantle cannot compete with the metallic filament lamp

Electric railways frequently require an extra supply of power owing to a holiday rush or some unusual event which crowds their cars to the utmost capacity Some of the roads have built their own portable substations consisting of cars provided with rotary converters or motor generators transformers and switch boards Recently one of the large electric manufacturing concerns has put out a stock portable substation of this type which may be moved to any section of the line and made ready for use at a moment's notice by connecting it to the high tension line

The annual Electrical Show at Madison Square Garden which was brought to a close last week was notable for its decorations. Nearly 40 000 yards of orange and white bunting were used to decorate the building The whole interior of the building was draped with bunting There was a canopy ceiling which was divided into panels, and candelabra were hung from the intersections of the panels Each candelabrum contained a cluster of twenty two 25 watt tungsten lamps encircled with amber-colored 40-watt lamps Six large chandeliers were placed over the center of the arena. These chandeliers were ten feet in diameter made up of art glass. Altogether the effect was superior to that of any previous exhibition

At the recent meeting of the International Association of Municipal Electricians a resolution was adopted favoring the grounding of secondaries in alternating-current systems The resolution calls attention to the fact that life and property have been destroyed from high voltages on alternating-current secondary systems, because of the failure of insulation between primary and secondary circuits, and that such dangers may be obviated by grounding the secondary and it demands the enactment of legislation requiring all alternating-current secondary systems to be grounded when by so doing the voltage between the earth and any part of the secondary systems will not exceed 250 volts.

A German investigator has found that the insulation resistance of coils made from bare aluminium wire depends upon the compression of the wire and also on its thickness The smaller the wire the less its insulation resistance This he thinks is due to the fact that the thick wires are soft, while thin wires are hard drawn He also finds that the resistance is considerably reduced while the coils are wet. He therefore suggests that in making coils of bare aluminium wire, the windings should be separated by non hygroscopic material Before winding the coils they should be wet so as to oxidize the aluminium After several days they should be dried in a vacuum and lacquered

The following method of impregnating field coils was recommended at the recent convention of the American Street and Interurban Engineering Association The wire is insulated with asbestos held in place by a cotton covering The coil is wrapped with porous tape, and then placed in an air-tight chamber and heated. The air in the kettle is exhausted and when the proper vacuum has been obtained melted asphaltum is permitted to flow in after which air pressure is applied, forcing the material into the interstices of the coil. When the coil is nearly cool it is brought to proper shape by means of clamping plates. When the clamps and tape are removed, the coil is covered with an insulation of varnished cambric.

SCIENCE.

Evelyn Briggs Baldwin, the Arctic explorer recently stated that he intended to make another trip to the Arctic and go on the ice drift over the apex of the earth and return between the east coast of Greenland and the west coast of Spitzbergen. It is a distance of two thousand miles and as a progress of no more than two miles a day can be made the journey will consume four years

Certain minerals exhibit the curious optical property known as asterism That is to say they show a star shaped figure when light is reflected from them or transmitted through them This is seen, for example, in the star stone a sort of sapphire and in the star ruby A note in Knowledge describes the asterism of mica. The photograph of a lamp flame taken through a plate of mica shows a six rayed star with six fainter radiations between Outwardly star mica resembles the ordinary form and shows the same phenomena under polarized light When examined under the microscope however the star mica is found to contain fine needles of another mineral and these are regularly arranged at angles of 120 deg To these needles the star seen by transmitted light is due Star mica has been found in the State of New York and at Burgess Hill Ontario

Henry Gannett, chairman of the United States Geographic Board Rear Admiral Colby M Chester U. S N formerly superintendent of the Naval Observatory, and O H Tittmann superintendent of the United States Coast and Geodetic Survey will compose the membership of the committee of the National Geographical Society which will pass on the records and proofs submitted by Robert E Peary to substantiate his claim that he reached the North Pole on April 6th 1909 At a meeting of the board of managers of the National Geographical Society on October 20th the records and observations furnished by Commander Peary were presented and Mr Gannett who had previously been appointed chairman of the committee on polar research named Admiral Chester and Mr Tittmann as the other members of the committee to determine Commander Peary's claims

In order to produce a cadmium spectrum of sufficient intensity for polarimetric work advantage is taken of the favorable properties of the silver-cadmium alloys by Dr T Martin Lowry On account of their isomorphism the two metals form an excellent series of alloys which are characterized by good mechanical properties and very high melting points. (An alloy with 60 per cent Cd melts as high as 700 deg C) In striking contrast to the behavior of the pure metal the alloy gives a steady arc which can be kept true to center by rotating the electrodes in opposite directions The spectrum shows the silver as well as the cadmium lines but these are so far separated that even with a low resolving power the slit of a spectroscope can be opened to its full width without any overlapping of the brilliant blocks of light which take the place of the usual lines

Arrangements are being perfected in New York for the incorporation of the American Radium Institute to be devoted to the treatment of cancer and similar diseases The Institute will be conducted much on the same plan as similar ones in Paris and London The work will be divided into various sections such as chemical physical medical and botanical with an expert in charge and it is believed that for experiments the laboratories of the Rockefeller Institute will be available Supplies of pitchblende for manufacture are to be drawn from Colorado and other Western localities where the initial processes of extracting the radium will be conducted It is announced that the institute is not in any sense commercial and that several of the scientists who are interested in it are not only giving their services free but are contributing from their own means to the fund which will be required to establish the plant

The observatory of Treptow has opened an international competition for the best photographs of the Leonid meteors taken from the car of a balloon between November 11th and November 16th 1909 The developed plates should be sent to the observatory anonymously but accompanied by a symbol which is repeated in a sealed envelope containing the place date and hour of exposure, the name and elevation of the balloon names of constellations in which meteors have been observed names of camera and lens with focal length and aperture, and the length of exposure The plates should reach the director of the observatory Dr F S Archenhold before January 1st 1910 The results of the competition will be published in the journal Das Weltall Three prizes consisting of a telescope and publications, are offered, but it is stipulated that the prize pictures shall become the property of the observatory The competition would have a better prospect of success if all photographs of the Leonids had been admitted. Balloons are still so rare that it is quite possible that not a single plate will be submitted

THE BRUSSELS POPULAR ELECTRICAL LABORATORY

BY DR ALFRED GRADENWITZ

Owing to the ever increasing importance of the applications of electricity it is small wonder that electrical laboratories should have been founded everywhere to afford a means of completing practical instruction In fact technical colleges and schools of all degrees are at present equipped with such laboratories

However the institute recently founded at Brussels by Dr Robert Goldschmidt the well known inventor and scientist is of an absolutely novel kind Realizing the inadequacy of book study and oral explanation for conveying a thorough understanding of experimental electricity Dr Goldschmidt provides an opportunity for experiment accessible to the general public desirous of observing the electrical phenomena which are so important for modern industry To attain this end he has created a popular laboratory of remarkably clear and simple disposition where lay people by starting from the most elementary facts will be able to acquaint themselves with any scientific problems relating to electricity

The original intention was to create some sort of museum of electrical invention and discovery organized on similar lines to the general museums of painting natural history and industry This however would have been quite insufficient as the object of any piece of apparatus exhibited would rarely be immediately apparent to the observer What was to be shown was not the principle itself but its demonstration and the method of conducting an experiment to demonstrate it and the best means of teaching the student this is to let him conduct the experiment himself This task was an extremely difficult one entailing as it did a rational classification of experiments such as should render them comprehensible In fact the main defect of any previous attempts in the same direction (made at London Berlin and Munich) had been the lack of plan and co-ordination

Every experiment had to be designed with a view to its being accessible to everybody in addition to forming part of a graduated course of inter-connected experiments Most of the apparatus used in connection with the Popular Laboratory had to be designed and constructed especially for the purpose and with a view to simplicity safety and solidity

On the ground floor of the laboratory (which was opened on the occasion of the recent twenty fifth anniversary of the foundation of the Society of Belgian Electricians) are installed apparatus for the fundamental experiments constituting the basis of modern electrical science These are performed with relatively simple means Visitors thus pass from the magnet stone to the properties of electro-magnets and the explanation of electro-motors from the generation of static electricity by the friction of glass and wax on to the working of Wimshurst machines on similar principles and to induction coils they then proceed to familiarize themselves with the phenomena of electrical discharge in various media (cathode and radium rays etc)

In the gallery are installed those apparatus which are required for the demonstration of the principles of electrical induction alternate currents and methods of electrical measurement

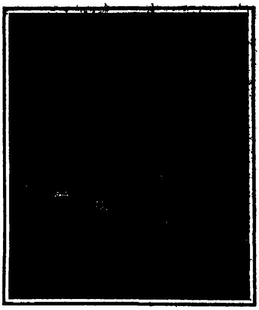
Each apparatus installed in these two departments of the laboratory is located in a glass case leaving free to the experimenter's hands only the instrument required for performing the experiment and thus avoiding any unnecessary contact liable to endanger the apparatus In three adjoining rooms are united the apparatus of precision and investigation as well as measuring instruments the handling of which requires a thorough knowledge of all the preceding comprising photometers precision bridges standards of measurement galvanometers wattmeters etc

On the ground floor in the center of the building are found such apparatus as will allow the visitor to familiarize himself with the most important measurements relating to motors and dynamos These two departments are different in character from the two preceding In fact visitors here find themselves in a laboratory where measurements and tests are performed by competent men By watching their work they will be able to grasp the mechanism of the experiment without being capable of performing it themselves Should however somebody sufficiently well instructed wish to experiment himself he would be allowed to do so under the supervision of an experienced operator

To the laboratory is connected a lecture hall behind which is installed a projector allowing visitors at any moment to inspect on the screen an extensive series of hundreds of views relating to scientific novelties This is actuated by a push button

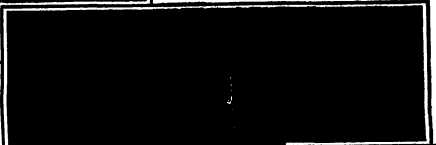
A special hall is set apart for industrial men to exhibit their products free of charge and a library containing the most important books periodicals and bibliographical files enables visitors to supplement by theoretical study the practical knowledge acquired in the laboratory

A mechanical workshop initiates those seeking such information in the construction of electrical apparatus Finally four small laboratories situated in the front building are to be placed at the disposal of specialists for use in original research work

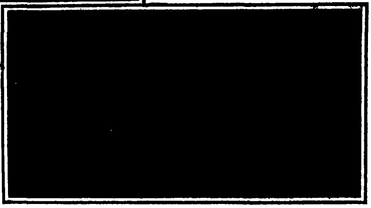


Apparatus for demonstrating current effects.

A row of static electrical machines



Apparatus for the study of natural and permanent magnets and terrestrial magnetism.



Apparatus for the study of radiation phenomena.

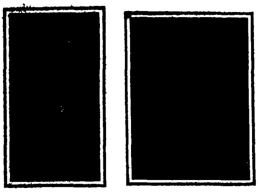
Apparatus for demonstrating attraction and repulsion of charged conductors.

Electrical measurement apparatus.

THE BRUSSELS POPULAR ELECTRICAL LABORATORY

A CURIOUS CHEMICAL GROWTH.

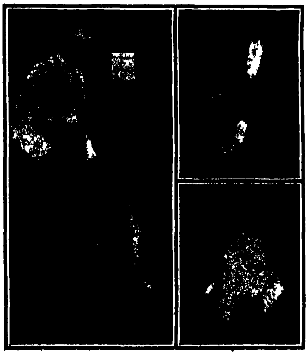
In the course of some experiments in qualitative analysis in the High School at Medford, Mass, a test tube containing solutions of several salts to which had been added hydrochloric acid and ammonium sulphite was set away in a closet for a few days Projecting vertically from the tube was a small piece of filter paper When the tube was removed a peculiar calash-shaped hood of ammonium chloride crystals was found resting on the paper



CURIOUS CHEMICAL GROWTH.

PLAYING WITH FIRE

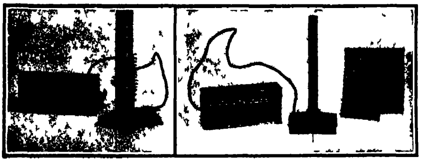
A can of gasoline can be handled as safely as a can of oil for liquid gasoline does not explode It is the gasoline vapor that is highly explosive when properly mixed with air The accompanying illustrations show the safety with which burning gasoline may be handled Fig 1 shows a man pouring burning gasoline from one can into another In Fig 2 he is blowing into the spout of a can of gasoline to which a match has been applied The little blue flame that ordinarily plays around the mouth of the can is transformed into a burning torch Fig 3 shows a pool of burning gasoline on the floor and two gasoline cans aflame, but there is no explosion



PLAYING WITH FIRE

MEASURING HOLES BY ELECTRICITY

One of the employees of a Chicago firm dealing in perforated metal to be used in flour mills has devised a simple measuring device for readily matching samples brought in by customers A tapering needle which is pushed into one of the perforations as far as it will go carries a brush that passes a series of electric contact pieces The latter are connected to a set of solenoids and when the circuit is closed by pressing a button one of these solenoids operates to uncover a number indicating the correct size of the hole



MEASURING HOLES BY ELECTRICITY

DIFFERENTIAL SPEED INDICATOR

The well known British naval architect Sir John I Thornycroft has designed an ingenious device for use on twin screw torpedo boats to indicate the relative speeds of the two propeller shafts A sphere is supported on and rotated by two cylinders whose axes meet at a point below the sphere The axis of rotation of the sphere varies its position with the relative speed of rotation of the cylinders A roller engaging the sphere tends to find a position where it does not slide In other words the axis of the roller moves into the plane of the axis of the sphere and a finger connected to the roller indicates the position of the axis of the sphere and thereby shows the difference of speed of the two shafts

DIFFERENTIAL SPEED INDICATOR.

Measurement of Distance by Aerial Electric and Sound Waves.

Debrix has invented a method of measuring a ship's distance from a shore station by taking advantage of the difference between the velocities of sound and electric waves A bell is set ringing and wireless electric waves are generated simultaneously on the ship The electric waves arrive almost instantaneously at the shore station and there set in motion a stop-clock The distance of the ship can be computed from the number of seconds indicated on the dial when the sound of the bell is first heard The computation is facilitated by the use of a table in which if necessary allowance may be made for the fraction of a second consumed in the operation of the receiving and clock starting apparatus In this way the distance of the ship can be obtained but not its direction or exact position If however the ship's auditory and electric signals are simultaneously received at two stations connected by telegraph the exact position of the ship on the chart will be found at the intersection of two circles drawn round the stations as centers with radii respectively equal to the ship's ascertained distances from those stations The general introduction of this system would greatly increase the possibility of aiding ships in distress—Prometheus

ACCIDENT PREVENTER

MOTORISTS ACCIDENT PREVENTER.

Attached to the wall at the corner of a narrow street leading in to the market place of Woodbridge Suffolk County England is a mirror which makes it possible for automobilists coming from either direction to look around the corner and thus avoid collisions The idea is being copied quite extensively by other English towns

Castings of Chloride of Zinc

By mixing a concentrated solution of chloride of zinc which must be of at least [illegible] deg Bé with highly heated zinc oxide we obtain a mass that is admirably adapted for the casting of various art objects

This preparation is at least equal in hardness to marble and takes a high polish as regards its behavior to exterior influence it excels marble altogether in its power of resistance being unaffected by the action of severe cold moisture or even boiling water and it is also fairly indifferent to the effects of very strong acids

This excellent casting mass is best produced by taking [illegible] parts of zinc white which has been highly heated (calcined) and after cooling kept in air tight glass vessels until needed and mixing it with 1 part of chloride of zinc solution of 55 deg Bé To effect the mixture we use a porcelain vessel in which we place first the zinc oxide then pour in the chloride of zinc solution and by stirring with a flat spatula produce a uniform mixture In mixing great care must be taken that no air bubbles occur in the mass for these would give rise to imperfect or defective castings The well stirred mixture is allowed to stand until it begins to become more fluid and it is then poured into molds in which it is permitted to harden If the zinc oxide before using is mixed with ground glass or with colors that exercise no chemical effect on zinc oxide (English red manganese chrome green red lead) colored castings can be produced

A SURVEYOR'S TELEPHOTO

The view herewith reproduced was photographed at a distance of a mile with a surveyor's level set up in front of a 4 by [illegible] camera The two instruments were connected light tight by winding a dark cloth around the contiguous parts An exposure of twenty seconds was made as the weather was cloudy It is somewhat surprising that no trace of the cross wires of the telescope appear on the picture

A SURVEYOR'S TELEPHOTO.

HIGH-SPEED DESTROYERS FOR THE UNITED STATES NAVY.

There was a time when the contractors of the United States seemed to be unable to live up to the exacting requirements of the government for the construction of torpedo boats and destroyers. There is no class of naval construction that calls for such high-class work as the building and equipment of a destroyer of 30 knots speed or more, and when our first destroyers were built most of the contractors failed to get the contract speed out of the boats

These failures however belong to the past and there is every reason to believe that the later destroyers built for our navy are fully up to, if they do not exceed the standard of the best foreign work, not even excepting the British

Evidence of this is afforded by the phenomenal speeds that have been realized in the recent trials of the 'Flusser and the 'Reid,' which made respectively 30 41 and 31 85 knots as the mean of a four hour trial the contract speed for which was only 28 knots and made their fastest miles respectively at a speed of 33 67 and 34 55 knots

The 'Flusser' and Reid' are two of the five destroyers bids for which were opened in September 1907 and which were awarded as follows The "Flusser and Reid' to the Bath Iron Works, Ltd Bath Me the 'Smith' and Lamson to the William Cramp & Sons Ship and Engine Building Company, Philadelphia Pa, and the "Preston to the New York Shipbuilding Company of Camden N J

The hulls of the Flusser" and Reid" were designed by the Bureau of Construction and Repair and are of the following dimensions

Length between perpendiculars	289 feet
Length over all	293 feet 10½ inches
Breadth molded at trial waterline	25 feet 1¼ inches
Breadth molded extreme	26 feet 4½ inches
Breadth extreme over guards	27 feet
Trial displacement	700 tons
Trial draft at this displacement	8 feet ½ inch

The contract allowance for machinery is 255 tons a penalty being assessed if this weight is exceeded The machinery however with water and spares carried on board weighed 228 tons so that the trial displacement was reduced by this saving of 27 tons less a hull overweight of 4 tons or a net weight saved of 23 tons The trial displacement therefore was fixed at 677 tons but on all of the trials of these vessels they were slightly deeper than this

The machinery was designed by the Bath Iron Works and consists of five Parsons marine steam turbines on three shafts the main high pressure being on the center shaft the starboard low pressure and I P cruising turbines together with the starboard backing turbine being on the starboard shaft and the port low pressure and backing turbine and the high pressure cruising turbine being on the port shaft The steam piping was so arranged that any of these turbines would run as the initial turbine All of these turbines are in one compartment

The two condensers were built up of plate each containing 4,000 square feet of cooling surface, measured on the outside of the tubes. The tubes were curved and expanded into the tube sheets, no packing being used The circulating water is provided by scoops into which the sea water rushes at great velocity when the vessel is under way, this method proving extremely satisfactory Small circulating pumps, however, were provided for use when the vessel is still in the water, or in getting under way There are the usual air pumps, feed pumps fire and bilge pumps, and oil pumps, etc, and an evaporating distilling apparatus was also provided with these pumps. All lubrication is forced, two duplex oil pumps being provided, together with an oil cooler

The boilers four in number, of the Normand return flame type, are placed in two water-tight compartments, there being a smokepipe for each of the four boilers The total grate surface is 346 67, and the total heating surface is 16 177 square feet Normand feed water heaters were also provided for each fireroom, and proved very efficient In each fireroom are two blowers, designed and built by the contractors and fitted with forced lubrication. These blowers give most excellent service, and have shown themselves capable of delivering air at 9 inches pressure in necessary volume Further than this, each fan, with its engine complete, weighs less than 900 pounds.

The contract specified that the vessels should be given standardization trials of not less than twenty runs over the mile, a four-hour full-speed trial, on which the speed shown should average not less than 28 knots per hour, a twelve-hour trial at 24 knots and a twenty four trial at 16 knots, and that the water consumption per shaft horse-power should not exceed 25.2 pounds on the 16-knot trial 16 5 pounds on the 24 knot trial, and 15 5 pounds on the full-speed trial, all of these guarantees being met with a comfortable margin

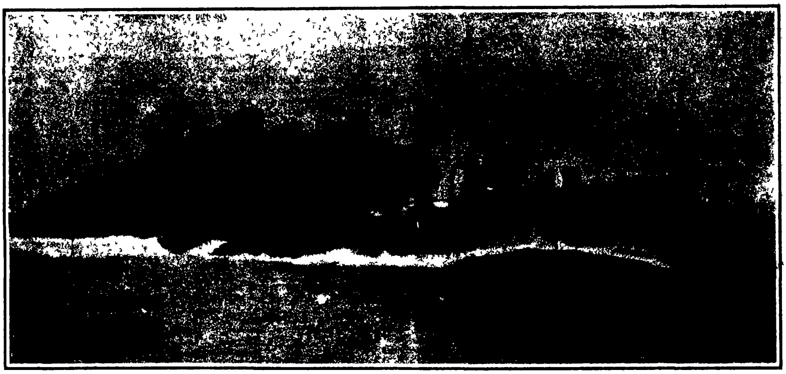
The following table gives the results of these trials

	"Flusser"	'Reid"
Speed fastest mile	33 67 knots	34 55 knots
Mean speed five high runs	32 67 knots	33 75 knots
Maximum shaft horse-power developed	14 400	15 140
Mean speed four hours	30 41	31 85
Speed best 15 minutes four hour run	30 85	32 25
Revolutions necessary for 28 knots	706	700
Revolutions maintained four hours	801	846
Shaft horse-power four-hour trial average	11 541	12,564
I P C. auxiliaries four-hour trial average	301	310
Total horse-power four-hour trial average	11,842	12 874

No limit was placed upon air pressure on the standardization trials. The contract provided, however, that an average of 5 inches could not be exceeded on the four-hour trials, and the 5 inch average was maintained but not exceeded on both vessels.

Both the "Flusser" and the "Reid" are equipped with Parsons vacuum augmenters, built by the Bath Iron Works, which performed very satisfactorily, as vacuums were maintained on both vessels, at all speeds, of between 28½ and 29 9 inches.

The horse-power developed (maximum) per ton of machinery is the highest we know of, namely, 66 on the "Reid" and 64.7 on the "Flusser" It should be noted the weight of machinery (228 tons) includes every part coming under cognizance of the United States Bureau of Steam Engineering, namely, the machinery complete, with tools, water in boilers, condensers, filter tank and piping, floors, gratings, ladders, handrails steam heat, non-conducting corking and lagging, and evaporators and distillers.



Copyright 1909 by N L. Stebbins.

Length, 293 feet 10½ inches, beam, 26 feet 4½ inches; draft, 8 feet. displacement 700 tons, horse-power 15,140. The motive power consists of five Parsons turbines driving three propellers. The "Flusser" (sister boat) on her trials reached a maximum speed for one mile of 33.67 knots.

THE "REID," FASTEST OF OUR DESTROYERS, MAKING 34.55 KNOTS ON HER TRIAL TRIP

The November Number of American Homes and Gardens.

The current issue of American Homes and Gardens contains many interesting features. Mr. Barr Ferree continues his series on notable homes and describes Villa al Mare, the country home of George Lee, Esq., at Beverly Farms, Mass John A. Gade contributes a very interesting article on the beauty and economy of stucco in the construction of the country house, or in the transformation of the old house. This article is illustrated by photographs showing the transformation of an old farm house into a habitable dwelling One of the most interesting subjects in the issue is that prepared by Francis D Nichols on a group of modern houses costing from $1,000 to $5,000 This article is profusely illustrated with photographs and plans and is particularly interesting to the man of modest means who wishes to build a home of modern style at small cost. Ralph C Davison writes on concrete ornaments for the garden and how to make them Kate Greenleaf Locke's article descriptive of four California bungalows is interesting, while Fritz Morris tells about the American Shetland pony S Leonard Bastin presents an article on a farming experiment by women Louise Shelton describes the garden of Hamilton House, and Robert Thompson tells of the beauties of 'Pine Haven," the summer home of Thomas B Van Buren Esq, at Kennebunkport, Maine. Alice M Kellogg solves some problems in home furnishings, and Charles Downing Lay tells about garden work around the home.

Prize for a Safety Automobile Crank.

A French association for the prevention of accidents in industrial work has offered $300 in prizes for a crank or safety device for hoists, cranes, and all forms of lifting apparatus, and also for explosion motors which shall in the first case, automatically stop the descent of the load, or in the second case, throw out of gear the driving action when not required. The invention remains the property of the competitor, who must himself be responsible for its due protection by patents. Drawings of competitive devices should be sent to the office of the Association des Industriels de France contre les Accidents du Travail, [illegible] Saint-André, Paris, France.

Correspondence.

THE INVENTOR OF THE STEAMBOAT

To the Editor of the SCIENTIFIC AMERICAN

I am indebted to a friend for the information contained in a recent issue of your journal relative to the Hudson-Fulton celebration in New York, in which under Fig. 1 you give a sketch of Jonathan Hulls's steam tug or boat, which you describe as being "proposed, but never built." With this statement I beg to differ, as it is quite contrary to actual facts.

You admit that the "complete description' is "of a practical steamboat," therefore I contend that the planning of a practical steamboat constitutes inventorship, if nothing "practical" existed previously This seems only fair argument, but I go further I am in the position to prove that the boat was actually built, from an official document viz Jonathan Hulls's treatise, published in 1737, as in this it is stated

"Whereas our Trusty & well Beloved Jonathan Hulls hath by his petition humbly represented unto Our most dearly beloved Consort the Queen Guardian of the Kingdom &c. That he hath with much Labour and Study, and at Great Expense *Invented* and FORMED a Machine for carrying ships & Vessels out of or into any Harbour against wind & tide, &c." And "the Petitioner hath made oath that he is the Sole inventor" etc., and he concludes his treatise by stating

"There is nothing in it but what is necessary to be understood by those that desire to know the Nature of that Machine which I now offer to the World, and I hope that, through the blessing of God, it may prove serviceable to my Country"

Now to prove practical results. I find in "The History of Progress in Great Britain," published in 1859 the following

"Thus we arrive at the time when in 1736 Jonathan Hulls' steam boat took a Sailing Ship in tow, and amid the wonder, doubts and jeers of the spectators made a great splash a loud noise and a black smoke yet managed to haul the cumbrous hulk along and gave promise that the child, which had distinguished itself by such an unheard of feat would one day become a giant of great strength"

What further or more convincing proof that the boat was actually built and proved practically successful can be required?

I would here mention that I have made a careful study of the claim of the many claimants from 1543 to 1807, a very lengthy period, and I challenge anyone to produce proof that will controvert Jonathan Hulls's right to the honor of being the inventor of the steam boat in 1736

My proofs consist of, among many others

1. Jonathan Hulls's specification No 556 (1736) old Law Series

2 Jonathan Hulls's treatise, written by himself (1737) Both still in existence at the British Museum and Patent Office Library

3 "History of Progress in Great Britain," published in 1859 Etc.

If you wish to pursue the subject further, I shall be pleased to submit many convincing proofs that the steamboat existed on this side, as also in America, long before the "Clermont,' which undoubtedly was not an invention of Robert Fulton's but merely the outcome of the inventive genius of one of Jonathan Hulls's methods of steamboat propulsion

I would be pleased to have a copy of your Hudson Fulton issue if you have a spare one, as I find some difficulty in procuring one here and in return I will assist you in reaching the actual indisputable facts as to who was the "inventor" of the steamboat.

J HOOPER HULLS

Manor Park, Essex, England

LEDUC'S FIGURES.

To the Editor of the SCIENTIFIC AMERICAN

In the number dated August 14th, 1909, you give a description of M St. Leduc's experiments for obtaining plant-like *forms*.

I believe I was the first, some thirty years ago, when I showed these forms to my friend Sir William Crookes, and explained to him how such experiments can be conducted Any of your readers having at his disposal some solution of silicate of potash or of soda and some metallic salts crystallized, sulphate of iron, of copper, of nickel, etc., can reproduce the experiments.

By filling a glass two-thirds with a solution of one of these silicates then adding distilled water to the very top, and throwing some small pieces of the metallic salt (which will fall to the bottom of the glass) into the solution, he will see, in a short time, plants growing in different forms, sizes, and colors, according to the salt employed. The copper one will give a blue, the iron a dark green, the nickel a light green, and a beautiful plant will be obtained with chloride of cobalt.

By varying the density of the silicate solution, different effects in form, size, and color will be obtained. If the solution containing the plants is kept well sheltered from the air by a good covering of the glass, these plants will keep any length of time

Paris, France GEORGES FOURNIER.

WHY DO WATCH SPRINGS BREAK?

To the Editor of the SCIENTIFIC AMERICAN

The mainspring of a watch does not unwind at a uniform rate, but intermittently It is subjected to a sudden jerk at every tick—four times per second for my Elgin watch This makes 345 600 times per day and over 126 million times per year This operating condition is analogous to others discussed in Kent's "Mechanical Pocket Book' under the heads of Relation of the Elastic Limit of Endurance under Repeated Stresses' and "Resistance of Metals to Repeated Shocks.'

Among other things it says "Another long known result of experience is the fact that rupture may be caused by a succession of shocks or impacts none of which alone would be sufficient to cause it. Iron axles, the piston-rods of steam hammers and other pieces of metal subject to continuously repeated shocks, invariably break after a certain length of service. They have 'a life' which is limited" Wöhler found in testing iron by repeated stresses (not impacts) that in one case 400,000 applications of a stress of 500 centners to the square inch caused rupture while a similar bar remained sound after 48 000 000 applications of a stress of 300 centners to the square inch (One centner = 110 2 pounds)

The mainspring of a watch is not only under a considerable tensile stress but also under a bending stress when suddenly released, then immediately stopped by the escapement mechanism It is then probable that its molecular cohesive power deteriorates in a manner similar to those quoted HENRY GETAZ.

Pittsfield, Mass

A MAGIC SQUARE

To the Editor of the SCIENTIFIC AMERICAN

The appended magic square is remarkable as containing the odd numbers in regular progression with

26	20	14	1	44	38	32
34	28	15	9	3	46	40
42	29	23	17	11	5	48
43	37	31	25	19	13	7
2	45	39	33	27	21	8
10	4	47	41	35	22	16
18	12	6	49	36	30	24

in the inscribed square So far as I know it has not been published before WILLIAM P DOYLE

THE BREAKING OF MAIN SPRINGS IN STORMS

To the Editor of the SCIENTIFIC AMERICAN

Respecting the breaking of main springs now discussed in the SCIENTIFIC AMERICAN it may be interesting to note what an old French watchmaker has to say regarding the rupture of springs in storms The following is a translation

"The influence of storms on the breaking of springs is certain, many watchmakers have observed it even ordinary rains may produce this effect. I have noticed it personally in quite a regular manner in the months of April and September which are generally rainy months, thirty per cent of the springs which I change in the course of the year are destroyed in these months by the influence of the rain This barometric influence acts much more on new springs than on those that have been working for a considerable time and these months are a critical period for testing their elasticity I have often been obliged after a short time to replace a spring that had thus been changed In one case I was obliged to renew the spring three times in the same day, though the springs had been carefully fitted"

Many of the watchmakers can cite cases of springs broken, not in a couple of pieces, but in ten or a dozen fragments, as if they had been divided by a saw Thus we come into the domain of electricity and watchmakers may be supposed to notice the effect without determining the cause

The quality of steel employed in the manufacture of springs and the care devoted to their tempering and annealing must be among the causes and it is for the makers of springs to give us information

Close observation has led me to believe that the contact of benzine or extreme oiling of the springs in stormy weather may not be completely foreign to their tendency to break.

Thus, when I change a spring during the critical period, I avoid passing it even rapidly into benzine I clean it by rubbing with a piece of peg wood and a rag slightly wet with fresh olive oil I do not wipe it and put it in without oiling as customary in ordinary weather I endeavor to substitute a slight lubrication for the oiling

This appears to me to be advantageous but I must acknowledge that it is not an infallible panacea It is to be hoped that other members of the profession will give the results of their experience

Brooklyn N Y CHARLES A BRASSLER

AN OPTICAL PHENOMENON

To the Editor of the SCIENTIFIC AMERICAN

In your issue of September 4th 1909 page 156 heading A New Speed Indicator for Marine Engines a device is necessary to enable engineer to correctly and intelligently interpret signals from the pilot or captain The camera device as described in a recent issue used on submarines when partly or wholly submerged would it seems put the engineer in a position which would enable him to interpret the signals by a visual comprehension of the location

The cost of installing one of the cameras on the upper deck so arranged as to give a clear front and rear view of the ship's situation with a reflection in the engine room should be inconsiderable

We must concede that there are times when the camera might be obscured by fog or smoke etc. At that time, if serviceable its utility might be greatest, but that is a time when attention is tense and is but a small proportion to the number of times when it would be effectively serviceable. The obscurity of the reflection *ipso facto* would be notice to the engineer to proceed cautiously and in case of doubt to ring for a repetition of signals

This letter is suggested by an experience I once had I was sojourning in the country in the lean to room of a log house The protection from the elements was a thin weather boarding As the fleecy flakes beat through the cracks and nail holes and with the cutting wind discomforted me I thought of a device whereby if I could not entirely obstruct I could at least reduce the force of the wind The next morning I bought and tacked some white drilling on the uprights about four inches from the weather boarding I was engaged in a perilous occupation and had been warned not to light my lamp without first lowering the shade in order that some unscrupulous owl meeting" participant might not make me the target of a 0 45 caliber Colt I neglected to reraise the shade and reentering my room my attention was arrested by a spot of green on the drilling Close investigation revealed in perfect miniature a reproduction in part of the landscape outside but reversed A small nail hole was the medium Though I have never experimented, I conclude the effect might be reproduced by tubes mirrors lenses etc so as to effectively show the surroundings of the ship in the engine room the engineer thus being partly in possession of the same information as the pilot or captain This suggestion is given for what it may be worth to you

Houston Tex G OC MACMANUS

[This suggestion and the experience from which it originates are very interesting The phenomenon described is that of the camera obscura and can be as well produced with a pinhole camera as with a lens hence the result from the hole in the roof A similar effect may be observed if a sheet of paper be held a few feet away on the dark side of a door which is opposite the window of a room a picture of the window and the scene outside if the light is good appearing inverted on the paper There are only two objections to the use of such apparatus in a ship's engine room one is that the engineer is unaccustomed to observing the effect upon the ship of the speed he is getting out of his engines and the other is that he has enough to do in regulating his engines to give the speed desired by the pilot without also having to gage and decide upon the necessary speed Also such a camera could hardly be arranged to look forward and aft simultaneously without complicated piping with a mirror at each bend to avoid the ship's gear and we should say it would not be desirable to remove the navigating responsibility from the bridge to the engine room In the case of the submarine it is different the navigator cannot be above deck when submerged so uses the periscope but he is still responsible for gaging the desired speed and instructing the engineer —ED]

The Current Supplement

The current SUPPLEMENT No 1765 opens with an elaborately illustrated and exhaustive article on the recent Paris aeronautic exhibition Mr F W Harbord's article on iron and steel and their relation to other industries is concluded An extract is published of an interesting report on the advantages of treating the water in swimming baths with electrolytic fluid The mechanicians and especially the watchmakers of three or four centuries ago invented many ingenious mechanisms which have been forgotten Some of these are described in the current SUPPLEMENT The dome just erected over the four great arches of the Cathedral of St John the Divine is an engineering feat of note, and is described and illustrated

HOW GERMANY MAKES FORESTRY PAY

BY FREDERIC BLOUNT WARREN

Germany has the highest developed system of forest management and conservation It has nearly 35 million acres of forest of which 31 9 per cent belongs to the State 1 8 to the Crown 16 1 to communities, 46 5 to private persons 1 6 to corporations and 2 1 to institutions and associations.

For each citizen there is a little more than three-fifths of an acre of forest and though 53 cubic feet of wood to the acre is produced in a year wood imports have exceeded wood exports for more than forty years, and 300 000 000 cubic feet valued at $80,000,000 or more than one-sixth of the home consumption, is imported each year

In forestry Germany has always led in scientific thoroughness the scientific knowledge has been applied with the greatest technical success, and it has procured an increasing forest output together with an enlargement of profits It will be interesting at the outset to state the European forestry theory the basis on which Germany and other nations have conducted their conservation work and statistics and summaries to come later to show that there has been a profit in the practice of the theory

In the cultivated forests of Germany the absence of underbrush and decayed logs and limbs the density of the forest and the even distribution of the trees often planted in long straight rows immediately arrest the attention One can walk with ease or drive anywhere among them except where the hills are too steep or stony or where the trees stand too closely together this always being the case in young woods The trees are not permitted to reach the full limit of their life and then as the result of decay to fall and remain rotting on the ground They are considered as wood capital, which adds interest to itself as long as the trees continue to grow, at first slowly when the trees are small more rapidly when they are of medium size and more slowly again when they become large When the trees die the wood interest ceases entirely and as they decay the capital is reduced The forester leaves this wood capital as long as the interest continues satisfactory Then, when the growth declines it is removed, the forester taking the trunks and limbs and the peasants gathering up the brush and often digging up the stumps, although these too are frequently taken care of by the forester and sold in the market to pay the cost of their removal In some German districts all the products are marketed In Mecklenburg a good layer of leaves and moss sells for $16 an acre In some sections a nominal sum is charged for brushwood In the Spessart Bavaria it has long been the right of peasants to gather the forest litter without charge Sometimes this permission applies to the gathering of nuts which are used as food for domestic animals

The United States has 164 000 000 acres of land in the 165 national forests besides 2 722 726 acres of State owned forests and 40 000 000 acres of woodland in the Philippines And the table below taken from official government statistics in a United States Forest Service bulletin is what our national forests return as a federal investment compared with the Saxon figures

In this statement the American may learn the difference between advanced European forestry at almost its highest profit and the lesser profit just beginning to accrue to the United States as a result of its endeavor to foster its wood producing resources Saxony's total area amounts to 5 780 English square miles of which almost one half is covered with private and governmental forest The last the State treasurer places as the highest revenue producer after the State railway and they exceed the revenues from all other sources taxation included The total quantity of timber cut in 1906 is estimated at 1 231 472 cubic yards (33 250 497 cubic feet) representing woods used for fuel and for all other purposes To this must be added a yield in brushwood cut and sold for fuel use principally of 190,415 cubic yards (5,140,906 cubic feet), raising the total quantity of timber and brushwood cut and sold to 1,421,887 cubic yards (38,391,403 cubic feet) for which $3,374,385 was obtained. This amount was increased by additional revenues from the leasing of meadows, hunting privileges, and other rights to the total of $3,483,616 Deducting from the total figures the cost of forest cultivation, with salaries and wages of the entire service included, amounting to $1 357 580 the net profit of $2,126,036 was added to the treasury in 1906. There is nothing unusual in this result as the ten preceding years show equally high figures, a few slightly exceeding the 1906 revenues, and others being lower in a very slight degree.

Country		Total Net Revenue from Government Forests	Expended per Acre	Net Revenue per Acre.
Saxony		$2,990,000	$3 05	$5.30
United States	1905 6	12,000*	0.007	*0.0001
	1906 7	164,659	0.0098	0.00066

* Represents deficit.

More and more accustomed to weighing questions, whether national or individual, in dollars and cents, there is contained for the American public in the above official statement the most potent argument for increased conservation of forest lands. Systematic state forestry began in Germany 150 years ago when the country felt the pinch of a wood shortage, but there were also contributory causes such as the effect upon agriculture and stream flow due chiefly to erosion Just across the border, France denuded of its forests was having trouble with its mountain torrents and the Germans opened their eyes to the dangers of floods in their own lands. Protective forests were provided for by Bavaria in 1852, by Prussia in 1875 and by Württemberg in 1879 Now all of the German states practise forestry with success

Part of forest tree nursery, Thüringen, Germany.

In Prussia the forests cover nearly 7 000 000 acres, and methods of management adopted call for a sustained yield In consequence, the productivity has been multiplied threefold in seventy five years In 1830 the yield was 20 cubic feet an acre in 1865 24 cubic feet, in 1890 52 cubic feet, in 1904, 65 cubic feet

Saxony has 430 000 acres of State forests, and its yield rose 55 per cent between 1820 and 1904 It is now 93 cubic feet an acre These increases are not limited to Germany, since other European nations notably Italy and Switzerland are now reaping large revenues from their timber lands

Forest tree nursery in the Thüringen Wald, Saxe-Gotha.

HOW GERMANY MAKES FORESTRY PAY

Where Saxon forests are yielding $5 30 an acre, those of Württemberg yield a net annual revenue of $6 and those of several smaller administrations exceed this' There are also a large number of private forests managed with great success whose revenues equal or exceed $6 an acre For 15 600 000 acres of state, municipal and private forests included in a canvass, it was found that the average net annual revenue an acre—from good bad, and indifferent land—was $2 40

The forests are managed largely in compartments, each of which, when the mature trees are considered ready for removal, is cut clean and planted with a new crop. Sometimes the compartments are located so that the cutting proceeds regularly in one direction as a protection against the prevailing winds, and at intervals of perhaps ten years, in which case the forest shows distinctly ten or twelve "age classes," arranged in a series of progressive heights. If a compartment is harvested and restocked each year, the number of age classes will of course equal the age to which the trees are allowed to grow "Cutting clean" is most commonly in use in pine and spruce forests of Germany These trees are mostly started in nurseries where the seeds are sown. In two years they are transplanted when six inches high. They grow in two or three years more to be twelve or fifteen inches tall, and then they are moved again to denuded fields and replanted about four feet apart, so that in a short time they will begin to crowd each other This condition compels the trees to grow tall and slender and to shed their lower branches, thereby permitting a growth of timber free of knots. The trees are usually planted in straight rows, and in about twenty years a thinning is necessary In spruce forests sometimes more than half of the trees are removed at the first thinning." These are sold for fire-wood poles, and various other uses. The fuel wood, laid at the roadside, brings about $2.25 a cord Subsequent thinnings are necessary about every ten or fifteen years Building material laid at the roadside brings nine cents a cubic foot, good spruce fuel wood $3 a cord On the poor sandy soil of Mecklenburg a thinning in Scotch pine when the trees are twenty years old yields only about $2 an acre, when forty, $5, when sixty, $10, when one hundred, $30 In the Erz Mountains, Saxony, thinnings when twenty years old bring $4, when forty, $15, when sixty, $80

Every product of the forests of Germany and southern Europe finds ready utilization This is due to the good market, population, low wages, and good roads. The effect of the market is everywhere apparent in the great economy of wood In hotels heat is a luxury for which guests often pay an extra charge Village and forest houses are seldom constructed of wood Walls of plaster or cement are the rule Floors are made of stone in many cases and tiles and iron take the place of shingles Wooden fences board sidewalks, and block pavements are uncommon

Yet the forests which cover one-fourth of the area, fall far short of the requirement. Germany imports more than 300 000,000 cubic feet of timber paying the duty of 28 cents for every 210 pounds of rough timber or logs and $1 15 for every 210 pounds, or one cubic meter (35 3 cubic feet) of dressed timber Germany's own production of timber amounts to more than 600 000 000 cubic feet. If Germany were to supply the deficiency from its own soil it would need an additional 20,000,000 acres The percentage of forestry soil would be increased from 26 to 40 per cent of its area It is doubtful if there are more than 2,500,000 acres for this purpose If every available spot were utilized and all the waste lands that are not well adapted for agriculture were planted in pine, spruce, fir and other trees it would require fifty years for them to be ready for market, and then the supply would not equal the demand Only Bavaria and Württemberg have a surplusage of home timber

It is the custom to buy individual trees rather than forests. There is a market unit of volume by which timber is generally purchased, called the "festmeter" It is a cubic meter (35.3 cubic feet) and is equivalent to 1.44 markets, or 19-inch standards, or about 288 feet board measure. In America large and small logs are scaled and sold together In Germany when the trees are felled, each one is marked with a number stamped in the butt. They are then sold by number in five or six classes according to size

Recently in the Hartz $22 65 a thousand feet, board measure, was offered for spruce tree trunks containing more than 300 feet $18 56 for trunks containing from 150 to 300 feet and for smaller sizes about $15 The live market for wood appears also in the number of metal railroad ties, being used in one-fifth of the entire mileage The use of wooden ties in recent years has been greatly encouraged however by the discovery of methods of impregnating wood with such preservatives as creosote, chloride of zinc, or sulphate of copper

As the forests are to be lumbered perpetually, the roads are made for permanency They consist often of stone, laid with much expense and not infrequently macadamized. In 1903 Saxony spent $175,000 on forest roads, and larger sums have been expended since by several States in the German federation. The roads at Geroldsau, in the Schwarzwald, are especially fine for forest hauling.

Germany's sawmills are usually small. Most of them would not cut more than 25,000 feet, board measure, in a day of ten hours Almost any fair-sized American sawmill cuts 100,000 feet a day But the small mill of Germany is permanent, being supported by perpetual crops of timber hauled to it by wagon or shot down streams. While some railroads carry logs, and rafts are still floated down the Rhine, Elbe, and other rivers, the method of hauling is very largely by wagon or by the old fashioned American "carry log" Along the Ens River in the Black Forest are located some of the largest mills, and to these the stock comes mostly on the railroad in long large logs, much of it being brought from Württemberg and Swabia. For each load of logs two cars are necessary

Preparing ground for a forest plantation in the Spessart, Northern Bavaria.

HOW GERMANY MAKES FORESTRY PAY

In Austria there are 24,000 000 acres of forest, of which 7 per cent belongs to the state. Private owners hold 58 per cent. As Austria has been independent of the German Federation only since 1866, its forestry system, in the main, has followed German lines Private forestry is encouraged by a system of taxation which relieves forests in which forestry is practised The total net annual state forest revenue is $5,000,909 The net yearly revenue of 21 cents an acre is comparatively low, due mainly to the facts that only 56 cents an acre is expended, and that most of the area is located in the rugged Alps and Carpathians, where administration and logging are costly The forest department was started in 1872, and reorganized in 1904 into three departments—administration proper reforestration and the correction of torrents and forest protection Forestry is successfully practised on 60 per cent of all the State forests, and on 82 per cent of the private forests The most conspicuous fruit of the State forestry is the restoration of the "Karst," a stretch of barren lands in the hilly country of Istria, of Trieste, Dalmatia, Montenegro and neighboring territory along the Adriatic Sea. It comprises 600,000 acres. This work has been carried on by the Forest Protective Service which was first created for Tyrol in 1856

In Hungary there are 23 000 000 acres of forest of which the State owns 16 per cent corporations 20 other institutions 7 5, and private persons 56 5 From ten to twelve million dollars worth of wood is annually exported, and the State forests yield $600 000 revenue Austria exports 3 670 000 tons of wood the greater part of it going to Germany About half of all the Hungarian forests is under working plans by which the annual cut of 1 000 000 000 cubic feet is regulated Forest planting is encouraged by the State nurseries, at which 10,000 000 seedlings are raised each year for free distribution and by bounties paid for forest plantations on private waste lands

Since dead timber is not left in any forests, there is but little loss from fires. In Saxony this is rarely more than $300 a year, Württemberg, about $650, and the Duchy of Baden with 240,000 acres had only 99 acres burned in nine years Fires are started mostly by careless smokers and workmen Locomotives cause about ten per cent In many places along the forested side of a railroad track there is a ditch about eight feet wide which is kept free of vegetation Frequently a strip of forest about a rod wide, running parallel with the railroad is prepared in the following manner A path along the edge of the woods is spaded about four feet wide In the forest about a rod from this and running parallel with it, a second path is made. Cross paths are made at intervals of about a rod These paths are free of vegetation and the ground in the strip is raked of leaves and twigs

In Germany forestry is a well established profession for which the candidates must prepare themselves thoroughly They must learn the science in a forestry school where the course of study requires much hard labor After graduation they must practise the science under masters for several years These masters are usually officers having charge of ranges A candidate takes first a position called in Germany "Forstreferendar" at a salary of about 1 200 marks ($286) In two or three years he is advanced to that of Forstassessor at 3 000 marks ($714) With successful service he may then be promoted to the position of "Oberförster" with a salary of 4 500 marks ($1,071) and a dwelling especially suited to his needs

THE HEAVENS IN NOVEMBER.

BY HENRY NORRIS RUSSELL, PH.D

THE principal astronomical news of the past month has been the finding of Halley's comet, which was announced by Prof Wolf of Heidelberg who succeeded in photographing it on September 11th. Faint images of the comet were later found on photographs taken at Greenwich two days before which were given relatively short exposures to avoid the danger of fogging by moonlight If the moon had been out of the way the comet might have been observed a week or two earlier

It is still an extremely faint object a mere nebulous disk with no trace of a tail visible only in very large telescopes and will remain faint until next spring

At the time of discovery it was more than 300 million miles from both the earth and the sun It is now approaching them and moving slowly westward in the heavens on the boundary of Taurus and Orion On December 1st it will be in opposition but will be too faint for small telescopes (about the 12th magnitude) It will continue to approach the earth until December 18th when its distance from us will be about 125 million miles After this it recedes from us as its motion about the sun is retrograde (i e in the opposite direction to that of the earth) and passes on the far side of the sun about March 24th 165 million miles from us Then it advances to meet the earth passes between us and the sun about May 17th and a few days later comes very near us within about 12 000 000 miles At this time the comet will be well observable in the early evening and in all probability an impressive object In a few days more it will double its distance from us and later it will gradually diminish in apparent size and brightness till it fades from view, though it should be telescopically visible until the end of 1910

It is not usual that the motion of a comet can be so accurately foretold within a few weeks of its discovery but Halley's comet has not really been discovered at all this time It has only been reobserved after an interval of more than seventy three years since it was last seen and after this long interval the time of its return was predicted with an error of about one day This would be a perfectly easy matter if the comet moved under the influence of the sun's attraction alone for then it would return at exactly equal intervals But the attraction of all the planets comes in to modify its motion and may alter its period by several years so that the actual calculation of a return is no easy problem and the success attained in this instance by the English astronomers Cowell and Crommelin (who have made an exhaustive investigation of the subject) is one of which science may legitimately be proud They have been no less successful in unraveling the past history of this remarkable member of our system but the story of that must wait till next month

Next among the events of the month from our standpoint must be mentioned the observations of Prof Campbell on Mount Whitney California These show no perceptible difference between the intensity of the absorption bands due to water vapor in the extreme red end of the spectra of Mars and of the moon It follows that the amount of water vapor in the atmosphere of Mars must be small compared even with that in the rarefied and remarkably dry air above the mountain at the time of observation

Prof Lowell's observations which indicated a perceptible amount of water vapor in the Martian atmosphere, were made under conditions which though very favorable, appear to have been hardly as good as those on Mount Whitney. What is the cause of the discrepancy it is too early to say, but it is just by the investigation of such differences that the art of observation is perfected, and it is not unreasonable to hope that the study of this case may lead us, not only to more definite conclusions concerning the atmosphere of Mars, but to still better methods of investigating the problem in future

THE HEAVENS

Turning to our map of the sky, we find Cassiopeia almost overhead The five brightest stars of this constellation, forming a group which looks like a badly dilapidated letter W, can be immediately identified

With the aid of the fainter star κ, we can see a resemblance to a rather less dilapidated chair, with its feet away from the pole, but the conventional figure of the Lady in the Chair" is turned just the other way, with feet toward the pole, and our initial illustration is one more example of the large share of the imagination in forming the constellation figures

Several individual stars deserve notice The line through the Pole star and β Cassiopeiæ points almost exactly toward the vernal equinox It may therefore be used as an indicator to estimate the sidereal time—remembering that it is above the Pole at sidereal noon to the left at 6 h below at 12 h, and to the right at 18 h With a little practice it is possible to read the sidereal time from this celestial bow band within about fifteen minutes. Then, by recalling that the sidereal clock agrees with the mean solar clock on March 22nd (or thereabout) and gains at the rate of two hours a month one can pass to ordinary solar time This is the simplest way to tell the time by looking at the stars

β Cassiopeiæ is also notable as a fairly near neighbor of ours having a parallax of about 0 10 sec, corresponding to a distance about two million times that of the sun or 32 light years. Two other naked-eye stars near by are nearer One of them η is marked on the map between α and γ This is a well known binary with a period of over 200 years and a parallax of 0 19 sec corresponding to a distance of 17 light years

The other, μ Cassiopeiæ, is the southern and fainter of a pair of stars which lie near the other corner of the parallelogram whose vertices are α, γ and δ Its parallax is about 0 11 sec and its distance 30 light years It is notable for its great proper motion 3 7 sec per year which corresponds to an actual velocity in space of 100 miles per second

The familiar winter constellations are beginning to return to the evening sky At any hour of observation, Taurus is well up in the east, and Orion is rising. Gemini too is on the horizon, and Auriga is well up in the northeast. Perseus, Andromeda, and Pegasus extend upward from this to the zenith, and beyond it.

The southern constellations are inconspicuous, but Mars and Saturn, the first near the meridian and the other east of him, add luster to the otherwise vacant region. The variable star Mira (o Ceti) is now near maximum. It may easily be found with the aid of the map.

The two bright stars below and to the west of Saturn and Mars are β Ceti and Fomalhaut, which are much more nearly equal in brightness than the map would indicate.

Another group of bright stars lies in the west. Deneb, in Cygnus, is highest up Altair is on the left, and Vega, the brightest of the three, below the first.

The Great Bear is low on the northern horizon, almost out of sight. Draco and Ursa Minor are above, and Cepheus higher still, close to Cassiopeia.

THE PLANETS

Mercury is morning star throughout November. He is best visible at the first of the month, when he rises about 5 15 A. M By the middle of the month he has drawn nearer to the sun, and rises about 6 o'clock, and soon after this he becomes unobservable without a telescope, with which he is best seen in broad daylight.

Venus is evening star, a long way from the sun, but very far south, so that she sets before 7 30 P M.

Mars, though past opposition and receding from us, is splendidly conspicuous in the evening sky, coming to the meridian about 9 P M at the beginning of the month, and 7 30 at its close.

Jupiter is morning star in Virgo and rises at about 3 A. M in the middle of the month Saturn is in Pisces about an hour east of Mars, and is on the meridian at 9 30 P M on the 15th

Uranus is evening star in Sagittarius, setting too early to be well observable On the 23rd he is in conjunction with Venus, being 2½ deg north of the latter

Neptune is in Gemini, and comes to the meridian about 4 A. M. during the middle of the month

THE MOON

Last quarter occurs at 4 P M. on November 4th, new moon at 9 P M on the 12th, first quarter at noon on the 20th and full moon at 4 A. M on the 27th, during the total eclipse of that date

This lunar eclipse is visible throughout North America and the adjacent regions, but at an inconvenient time for the amateur, in the small hours of the morning

The moon enters the earth's penumbra at 1 12 A M eastern standard time and first reaches the full shadow at 2 11 At 3 14 she disappears completely in it, and does not begin to emerge till 4:37 This is an unusually long duration, due to the fact that the moon goes almost centrally through the earth's shadow which itself is larger than usual, as the moon is near the earth

At 5 38 the moon finally leaves the shadow, and exactly an hour later she gets clear of the penumbra, and the eclipse is over

The moon is nearest to us on the 25th, and farthest off on the 9th She is in conjunction with Neptune on the 2nd, Jupiter on the 9th, Mercury on the 11th, Venus on the 16th, Uranus on the 17th, Mars on the 22nd, Saturn on the 23rd and Neptune once more on the 30th

Carbon Safety Ink —This ink is really no more than a sort of India ink kept in solution It may be made by rubbing down 10 parts of lampblack, 10 parts of gum, 5 parts of oxalic acid, and 200 parts of water, taking at first but little water and only adding the remainder after the thick mass has become uniform.

Patent Department

AN IMPROVED PLANTER

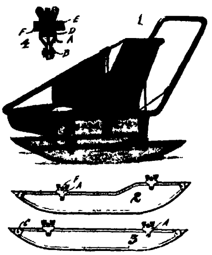
Pictured in the accompanying engraving is a planter provided with a seed box, in which there are no springs to become chocked or gummed by seed or dust. The seed-distributing mechanism is adaptable for seeds of different sizes, and may also be adjusted to plant seeds at greater or shorter distances apart. The seeds leave the box so close to the ground that there is no danger of their becoming scattered. The frame of the machine is supported on a traction wheel *A*, which, through the medium of suitable gearing, operates a bevel gear *B*, affixed to a vertical shaft which runs through the seed box *C* Secured to the forward part of the seed box is a share *D*, which plows a furrow in advance of the seed box, while a pair of hoes *E*, converging rearwardly, serve to cover the seed with the earth plowed up by the share. A disk *F* is secured to the shaft which runs through the seed box and is adapted to rotate in contact with the bottom plate of the seed box. The disk is provided with a series of perforations, adapted to be brought successively into engagement with an aperture *G* in the bottom of the seed box. A cut-off *H* bears against the disk *F* immediately above the aperture *G* A rod attached to the cut-off *H* extends through the top of the seed box, and is normally pressed downward by means of a spring *J* As the disk *F* revolves, it carries one seed at a time to the opening *G*, through which the seed falls into the furrow The machine is supplied with disks having perforations of different sizes, suitable for seeds of various sizes, and the intervals between the perforations vary in the different disks to provide the proper spacing of the seeds planted If desired two or more seed boxes may be connected to the traction wheel, so that a number of rows may be planted at the same time. The inventor of this planter is Mr August Brinkoeter, Floresville Texas.

AN IMPROVED PLANTER.

◆

SLEIGH-RUNNER ATTACHMENT FOR BABY CARRIAGES.

A patent has recently been issued disclosing a new form of sleigh-runner attachment for baby carriages, which may readily be applied to an ordinary go-cart or baby-carriage or a child's wagon, to permit of using it over snow-covered walks The accompanying engraving indicates the form of this attachment The runners, which are made of T iron, consist of a horizontal upper and lower member, with the ends of the lower member curved upward and braced by means of plates *C* The axles of the carriage are made fast in a pair of saddles mounted on each runner The form of the saddle is shown to better advantage in the cross-sectional view, Fig 4 It consists of a yoke *A*, which fits over the horizontal portion of the T iron, and it is made fast by means of a bolt *B* on the under side. A pair of bolts *D* with flat heads *E* resting on top of the runner project upward through the yoke to receive a strap *F* which is clamped down on the axle by means of a pair of thumb nuts. When it is desired to attach the runner to a folding go-cart a sleeve is preferably fitted over the axle and this sleeve is clamped between the strap and the yoke Fig 1 shows a form of runner used on vehicles which have rear wheels of larger diameters than the front ones It is quite essential to have the rear as well as the forward end of the runners curved, because this enables one to lift the forward end of the baby carriage when mounting a curb, or when it is desired to make a sharp turn. It also permits of lowering the carriage from a step or the curb The runners may be quickly applied or removed by merely turning the thumb nuts, and they are applicable to any type of go-cart, owing to the fact that the saddles may be adjusted along the upper member of the runner, and made fast at the desired point by tightening the bolt *B* The inventor of this attachment for baby carriages is Frederick C Kengeter, 2656 Pitkin Avenue Brooklyn N Y



SLEIGH-RUNNER ATTACHMENT FOR BABY CARRIAGES.

◆

COMBINED FRICTION AND JAW CLUTCH.

The principal advantage of a friction clutch is that it permits the shaft under load to be brought gradually up to the speed of the power shaft, thus eliminating the shock of starting However the friction surfaces are liable to wear out rendering the clutch useless in a short time Except for starting and stopping the jaw clutch is better because it provides a positive engagement of one shaft with the other The accompanying engraving illustrates a clutch in which it is aimed to combine the advantages of both forms The power shaft is indicated at *A* and the load shaft at *B* Mounted on the shaft *A* is a hub *C* formed with a flange to which the disk *D* is bolted Projecting through a central aperture in the disk *D* is an annular jaw *E* The disk *D* at its periphery is formed with an annular flange which incases part of the clutch mechanism A ring *F* is fitted within this flange and keyed to it The ring has openings at suitable points to receive wooden blocks *G* which protrude from the opposite faces of the ring Keyed to the shaft *B* is a member *H* on which is fitted a sleeve *I* formed with a flange at its inner end A series of bolts *J* are fitted between this flange and a ring at the opposite end of the sleeve. A ring *K* is mounted to slide on the sleeve *I* and the bolts *J* pass therethrough while coil springs on the bolts *J* bear against the ring *K* tending to press the latter outward The flange of sleeve *I* and ring *K* have annular bearing surfaces adapted to engage the blocks *G* at opposite sides They are pressed into engagement by means of levers *L* fulcrumed to the ring at the end of the sleeve *I*, and links *M* are fitted between the levers *L* and the ring *K* The levers *L* are connected by links to a sliding collar *N* operated by a lever *O* fitted with a split collar in the usual manner The collar *N* slides on a sleeve *P*, which at its inner end is provided with jaws *R* These jaws are adapted to slide in recesses at opposite sides of the member *H* and the jaw *E* In operation when it is desired to separate the jaws the lever *O* is operated to draw the collar *N* back on the sleeve *P* This serves to press the flange *I* and ring *K* against the friction blocks *G*, thus taking the load off the jaws, and when the collar *N* comes into contact with the flange *S* at the end of the sleeve *P*, the jaws *R* are withdrawn from engagement with the clutch member *E*, after which the friction surfaces are released owing to the toggle action of the links connecting to the collar *N* When throwing the clutch into engagement the reverse takes place The friction surfaces are first thrown into contact before the jaws *R* move into engagement with the recesses in the clutch member *F* It will be understood that the frictional engagement is only momentary serving to bring the load shaft approximately up to speed and thus obviating the shock of starting and the danger of breaking the clutch jaws The inventor of this combined friction and jaw clutch is Mr Charles Stewart Hook 79 Victoria Street, Toronto Ontario Canada

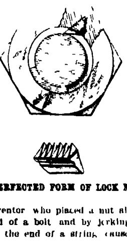
COMBINED FRICTION AND JAW CLUTCH.

◆

A PERFECTED FORM OF LOCK NUT

Of the many kinds of lock nuts which have been, or are at present manufactured few have the simplicity and surety of the one recently patented by Mr William Jacobus, and soon to be placed on the market. The accompanying engraving shows at a glance the extreme simplicity of this invention, which consists in cutting from an ordinary nut a small wedge-shaped section that when it is put back in place and the nut is screwed up jams tightly against the thread as soon as an effort is made to unscrew it. When it is desired to remove the nut the wedge can be released by a pin or piece of wire and the nut can be unscrewed

Two capital advantages of this new nut are that it practically is in *one piece* resembling in general appearance any ordinary nut and secondly the fact that vibration tends to tighten instead of loosen it. An excellent demonstration of this latter fact was given us by the inventor who placed a nut about half way up the thread of a bolt and by jerking the bolt up and down on the end of a string caused the nut to travel to the end of the thread where it was effectually locked

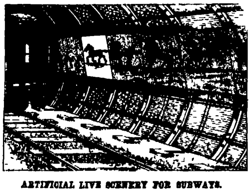


A PERFECTED FORM OF LOCK NUT

◆

ODDITIES IN INVENTION

MOVING PICTURES FOR SUBWAYS Moving pictures are produced, as is well known by a film traveling with intermittent motion before a projector or lantern which throws successive views on the screen The same result could be obtained if the pictures were stationary and the audience itself were in motion so as to view the pictures successively An ingenious inventor has hit upon this scheme to relieve the monotony of subway travel He proposes to mount a continuous band of pictures at each side of the subway and have these pictures successively illuminated by means of lamps placed behind them The circuits of the lamps would be successively closed by means of a shoe upon the subway car engaging contact plates at each side of the track The accompanying illustration indicates the method of accomplishing this result.



ARTIFICIAL LIVE SCENERY FOR SUBWAYS.

◆

Fluid Siccative—60 parts of old linseed oil are boiled with [illegible] parts of carbonate of manganese until viscid The temperature required is about 5[illegible] deg F (280 deg C) The mass should then be dissolved in 120 parts or more of oil of turpentine

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

TROUSERS SUPPORTER.—H. Irvin, New York, N. Y. In this construction an elastic belt is wholly contained within the trousers, and has wire loops or their equivalent attached to its opposite ends and adapted to engage over a button at the front of the trousers in holding them in place. The invention also provides in connection with the belt adjacent to its ends drawers supporters which engage with the supporting loops of the trousers when the ends of the belt are detached and prevent the passage of the ends therethrough.

Electrical Devices.

ELECTRIC SWITCH.—H. D. Grinnell, New Bedford, Mass. The switch is more especially designed for turning on or off the gas supply for the lamps of an automobile or other motor vehicle and at the same time controlling the igniting devices for said lamps. The result is obtained by the use of a manually-controlled switch shaft having an arm carrying a pinion in mesh with an internal gear wheel formed of alternating insulated and contact making sections.

ELECTRICALLY OPERATED AUTOMATIC SWITCH.—W. A. Lacke, Chicago, Ill. One advantage in this device is the fact that the solenoids are dead at all times except when in the act of moving the damper. In case a contact closes and the damper regulating mechanism is in consequence actuated, the closure hereafter of the same contact will have no effect and will not waste any current. It is only when another contact is closed and current is needed for moving the damper in the opposite direction that any current whatever is able to flow.

ELECTRIC LIGHT BRACKET.—L. L. Darby, New Orleans, La. The invention relates more particularly to brackets which include a body provided with a bulb-carrying socket, clamping jaws for removably securing the feed wires in place on the body, and a ring, the latter serving removably to engage the jaws to fasten the same firmly in place.

Of Interest to Farmers.

ATTACHMENT FOR RIDING CULTIVATORS AND OTHER AGRICULTURAL IMPLEMENTS.—C. N. Simpson, Bryan, Texas. This attachment may with slight changes in the implement be placed upon a riding plow, a riding cultivator, or a planter, and enable an exact control so that the plows proper or cultivator blades may be instantly changed in adjustment to lower or raise their points in conformity with changes in inclination of the surface of the ground, thus insuring equal proper depth of furrow or agitation of soil in level and undulating ground, and when the implement is turned at a fence row.

COTTON MARKER FOR BALES.—O. W. Long and E. Otidys, Lindsay, Okla. In the present patent the invention is an improvement in cotton markers for use on bales of cotton, whereby the bale when being tied out will operate to permanently bind the marker to the bale by the ties, which hold the bale in compression.

Of General Interest.

ENVELOP.—N. J. Macdonald, Irish Cove, Nova Scotia, Canada. This invention refers to certain improvements in envelops and more particularly to a special flap construction, whereby after the envelop is sealed it is very difficult, if not impossible, to gain access thereto without leaving evidence of the fact that the envelop has been tampered with.

APPARATUS FOR THE BACTERIOLOGICAL TREATMENT OF SEWAGE AND THE LIKE.—O. A. Lucas, 75 Rue Voltaire, Levallois-Perret, Seine, France. The invention is an improvement in apparatus for the bacteriological treatment of sewage, fecal matters, domestic waste water, and the like. It may be installed in dwelling houses, thus permitting the destruction on the spot and in a complete manner of the organic germs contained in sewage. It is an improvement over a prior patent granted to Mr. Lucas and treats sewage successively by anaerobic and aerobic fermentation and oxidation.

FURNACE FOR SMELTING ORES.—W. Kemp, Tucson, Ariz. Ter. This invention relates to furnaces and admits of general use, but is of peculiar value in furnaces provided with water jackets and adapted to be used in connection with burners for smelting ores. Upon actual test this furnace has proven more efficient than the old style furnaces.

HOLDER.—I. Hunzelberg, New York, N. Y. The object here is to provide a holder or box for containing court plaster, postage stamps and like articles, and arranged to accommodate a large number of articles in a comparatively small space, to allow convenient removal of an article as required and to protect them against deleterious influences of moisture.

BALE TIE.—H. O. Low, Bridal Veil, Ore. The purpose of the invention is to provide novel details of construction for a bale tie, especially well adapted for holding a wire strand bound tightly around a bundle of shooks, lath, shingles or other material, to adapt such material for convenient handling and transportation.

FIRE EXTINGUISHER.—D. H. Conkling, Fort Pierce, Fla. The invention relates to improvements in extinguishers in which a mixture of sulphuric acid and bicarbonate of soda is combined to form carbonic acid gas, which possesses powerful extinguishing properties. Means are provided whereby the extinguisher may be instantly and automatically recharged by the returning of the extinguisher receptacle to its normal or upright position.

TYPE WRITER CABINET.—J. D. Cleaton, Atlanta, Ga. The object of the inventor is to provide an office desk of the usual form with a compartment at one side of the central knee space with means to assist in lifting the typewriter from the compartment, up through the top of the desk and to dispose it over the knee space, to be further shifted if desired to a more central position.

NON-REFILLABLE BOTTLE.—J. S. Bromhead, New York, N. Y. The invention provides a bottle arranged to insure a steady flow of liquid from the bottle when tilting the same, and prevents refilling of the bottle by unauthorized persons after the bottle is once emptied of its original contents. It relates to non-refillable bottles such as shown and described in Letters Patent of the U. S., formerly granted to Mr. Bromhead.

Hardware.

FLUSHING DEVICE FOR WATER CLOSET TANKS.—J. F. Young, Owatonna, Minn. The purpose of this inventor is to provide an independent automatic locking device adapted for use in connection with the customary float locking supply valve, and which, although it may be used for other purposes, is especially designed to be employed in water-closet tanks.

SOCKET PIECE FOR STUDDING, ETC.—W. P. Rice, Lowell, Ohio. The object of the invention in this case is to provide a device especially adapted for securing the beveled end of a piece of timber against the side of another piece, as for instance in securing the legs of trestles to the body portion.

RAZOR BLADE SHARPENER.—D. M. Perine, Pittsburg, Pa. An object of this improvement is to provide a device by which the blade may be sharpened evenly, such result being obtained by disposing the blade holder on a pivot centrally located between two sharpening disks.

STRAP SEAL.—S. Baruch and M. Dessauer, New York, N. Y. The invention comprehends a fastening for holding together the ends of the strap or straps to be connected, and a seal comprising a plate of sheet metal bent around the overlapping portions of the strap or straps and secured by aid of eyelets so as to conceal and protect the fastening.

PADLOCK.—L. A. F. C. Byrne, Lahore, Punjab, India. More particularly the invention relates to a padlock of the kind comprising a casing, a rotatable shackle mounted to project partly from the casing, a slidable member which in a predetermined position holds the shackle against movement, and key-operable tumbler levers controlling the slidable member.

Heating and Lighting.

FURNACE FOR UNIFORMLY HEATING METALS.—W. N. Best, New York, N. Y. The invention has reference to certain improvements in furnaces adapted for use in heating forgings, castings, or the melting of metals, and the object of the inventor is to so construct the furnace that the temperature of all parts of the heating chamber will be the same.

Household Utilities.

STRAINER.—G. F. Grimm, Evansville, Ind. The main object in this case is to provide a device by which a strainer may be supported on a coffee pot of ordinary construction without changing the latter in the least. A further object is to provide an adjustable support which may be applied to pots of different sizes.

CUSPIDOR.—J. H. Gregory and F. M. Stewart, Farwell, Mich. The invention has in view a cuspidor having side portions hinged at the top to swing outwardly from the base and provided with a hopper bottom inclining from the center toward each hinged side portion, to insure ready discharge and easy cleansing.

Machines and Mechanical Devices.

MECHANISM FOR THE PRODUCTION OF A CONSTANT MIXTURE OF GAS AND AIR.—F. W. Wolff, 23 Melanchthonstrasse, Berlin, Germany. This mechanism is for use for the production of a constant mixture for illuminating purposes with the employment of a suction and forcing apparatus, the action of which is regulated in dependence upon the consumption, and which produces and sucks the mixture at low pressure and sends it at an increased pressure into the service pipe.

PHONOGRAPHIC REPRODUCER.—R. B. Smith, New York, N. Y. Primarily the invention pertains to phonographic reproducers, but may also be used in connection with phonographic records and generally in all relations where there is a stylus lever controllable by, or employed for the purpose of controlling, a diaphragm in order to record or reproduce sounds.

DISPENSING MACHINE.—C. M. Jewell, Canastota, S. D. This machine is particularly adapted for dispensing sheets, envelops, picture cards, packages of cards, or similar sheet material, and relates more particularly to the operating and controlling means for delivering the articles to be dispensed to the discharge opening.

COMBINATION HARNESS AND WARP STOP-MOTION.—H. Anner and M. J. Marsh, Phillipsburg, N. J. The invention refers to looms and provides motion arranged to stop the loom in case a warp thread breaks, the breaking of a warp thread allowing its heddle to drop and close an electric circuit at the time the heddle frame moves into lowermost position, the electric circuit controlling an actuating device for the usual stop motion of the loom.

DOGGING DEVICE.—O. M. Karns, Memphis, Tenn. The logs being sawed are secured by dogs to knees adjustable upon head blocks. After each cut these knees are advanced on the head blocks so as to present the log to the saw to saw another plank. The log is held to the knees by dogs. The dogs used in practice do not hold the logs rigidly on the carriage and are apt to become dislodged. The object here is to provide a device which will enable the logs to be securely held against the knees.

Musical Devices.

SELF PLAYING PIANO.—F. B. Long and E. A. Tapps, Los Angeles, Cal. The intention here is to provide an effective connection between the pneumatic and the hammer action to allow playing the piano automatically or by hand power and without interference by the connection. This is obtained by use of a lever, connected at one end with the movable member of the pneumatic, and an auxiliary lifter rod for engagement with one of the members of the hammer action to lift the rod resting on the free end of the lever.

SOUNDING BOARD FOR PIANOS.—F. B. Long, Los Angeles, Cal. In this patent the purpose of the inventor is to provide a new and improved sounding board for pianos, provided with manually adjustable devices for maintaining the original crown of the sounding board and for increasing the singing quality and the volume of the tone.

Prime Movers and Their Accessories.

BELT GUIDE.—G. H. Tunias, Sherman, N. Y. The invention relates to belt guides, the more particular purpose being to provide an efficient form of belt guide for use in connection with portable engines and including means whereby in a few minutes, various adjustments may be made relative to the position occupied by the moving belt.

Railways and Their Accessories.

RAILROAD-TIE AND RAIL-FASTENER.—J. P. Donovan, Georgetown, Ky. This tie is provided with rail-seats which serve to prevent lateral movement of the rails, and the improved rail fastener prevents vertical separation of the rails from the ties. Thus the fastener coacts with the ties in holding the rails secured against both integral and vertical movement of the rails relative to the ties.

CONCRETE RAILWAY TIE.—J. P. Donovan, Georgetown, Ky. The invention comprises a tie with raised shoulders on the upper side which are separated to provide rail seats and with transverse openings below the seats, for receiving rail fastenings, and reinforcing members arranged longitudinally of the tie in two horizontal sets, one near the base, the other near the top of the tie, and comprising metallic rods having end disks wholly imbedded in the concrete.

APPARATUS FOR MOLDING CONCRETE RAILWAY TIES.—J. P. Donovan, Georgetown, Ky. Mr. Donovan's invention is embodied in a box-like body or mold proper provided with certain accessories, whereby concrete railway ties, also fence posts, building blocks, and the like may be produced with facility and despatch. Ten molds may be used for each shift, so that concrete may take initial set in the first of the series while concrete is being placed in the last.

Pertaining to Vehicles.

VEHICLE-WHEEL.—J. H. Scott, Jersey City, N. J. This is an improvement in wheels in which a resilient connection between the spokes and the rim of the wheel is effected in order that the use of pneumatic or cushioned tires may be unnecessary. To this end a wheel is provided, a hub having a series of radiating spokes secured thereto, a rim, and a cap fitting over the outer end of each spoke having a curved spring attached intermediate its length, with its free ends connected to the rim.

ATTACHMENT FOR AUTOMOBILES.—H. S. Delamere, Ferndale, Cal. The aim here is to provide an attachment for automobiles by means of which one or both of the driving wheels will actuate a removable drum upon which a line can be wound up, to draw the automobile out of a mud hole or sand pit, and up steep grades or hills.

WHEEL.—A. C. Gillam, Hicksville, Ohio. The object here is to provide a pneumatic wheel with a punctureless tire. The annular pneumatic tubes are protected from injury, being housed in by an inner ring and body plates, and are subject only to pressure strain and not to frictional wear. This permits the inventor to make the air chambers of the pneumatic cushioning tubes relatively large, it being understood that these tubes may be made of any suitable material.

Designs.

DESIGN FOR WINDOW SHADES AND THE LIKE.—A. A. Boeck, New York, N. Y. Mr. Boeck has designed ornamental patterns for fabric for window shades of three different types which display artistic and original taste and form of varied and beautiful effects.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

NEW BOOKS, ETC.

The Poe Cult and Other Poe Papers. By Eugene Didier. New York: Broadway Publishing Company, 1909. 16mo., 301 pp. Price, $1.15.

The twenty-three separate articles comprised in this volume have been published in various American magazines during the last thirty-five years. Among the subjects treated are "The Poe Cult," "Poe, Real and Reputed," "The Boyhood of Edgar A. Poe," "Poe's Female Friends," "The Loves of Edgar A. Poe," "The True Story of Poe's Death," "The Poe Monument," "Portraits of Poe," "The Poe Mania," "The Truth about Edgar A. Poe," "Recollections of Poe by the Witnesses of His Life," "The 'Discoverer' of Poe," "Poe and the University of Virginia," "The Centennial of the Birth of Edgar A. Poe." The book is a very interesting one, and reflects great credit upon the author and shows an extraordinary grasp of the whole subject of Poe.

The Solicitor's Patent Practice. By George Frederick Emery. London: Effingham Wilson, 1909. 16mo., 245 pp.

The aim of this book is to provide a handbook for ready references on British patent law for the use of solicitors, it not being the purpose of the author to include subjects which would make it of particular value to the patent agent. Much general information is contained in the book, but it is of course impossible for the author in a little over two hundred pages to treat fully the many questions in patent law which a solicitor must be informed concerning, and on the principle that a little knowledge is dangerous it would not be wise for a solicitor to place the volume on his shelf except with more comprehensive works. When referred to in connection with some standard work "The Solicitor's Patent Practice" should prove useful.

Statics by Algebraic and Graphic Methods. By L. J. Johnson. New York: John Wiley & Sons, 1909. 8vo., 170 pp., 13 plates. Price, $2.

The former edition of this work is so well known as one of the first treatises on statics to include in a complete and practical way the valuable graphical method that it is only necessary now to remark upon the additions and alterations. These include a detailed scheme tested by the author in his classes, for assigning individual data for the exercises and a copious collection of practice problems with answers. A short syllabus is also added to facilitate review and enforce certain points. The author's arrangement is well calculated to give a facility in applying the subject valuable in engineering practice.

Strength of Materials. By Arthur Morley, M.Sc. London and New York: Longmans, Green & Co., 1909. 8vo., 480 pp., fully illustrated with diagrams. Price, $2.50.

This book, like the foregoing, is intended primarily for engineering students and differs from other works on the subject principally in the completeness with which demonstrations involving even simple mathematical problems are worked out. In many books the method is indicated and a good deal then left to the imagination, which is sometimes confusing to those whose mathematics are limited or out of practice. The result of important recent research work bearing on strength of materials has been included, reference being given to more complete records of the tests. Other important subjects are more fully treated than usual, such as the strength of rotating disks and cylinders, the bending of curved bars with application to hooks, links, etc., and the stresses and instability arising from certain speeds in running machinery, all of which are of practical application and valuable to the engineering practitioner.

Robert Fulton and the Clermont. The Authoritative Story of Robert Fulton's Early Experiments, Personal Effects, and Historic Achievements. Containing Many of Fulton's Hitherto Unpublished Letters, Drawings, and Pictures. By Alice Crary Sutcliffe. New York: The Century Company. Pp. xv, 367, 8vo., cloth. Price, $1.20.

Among the many lives of Fulton which have been written this by his great-granddaughter is unique, because of the many hitherto unpublished letters of Fulton which it contains: letters which throw much new light on the work and aims of that distinguished man. It also contains reproductions of several drawings, which are of great interest and even future value in establishing certain disputed facts about the engines of the "Clermont."

These drawings are from four folios of Fulton's original drawings now in the New Jersey Historical Society's possession. The work throws much light upon the nineteen years which Fulton spent in Europe, and it brings us into intimate touch with the personal life and the private character of the inventor Judged from the standpoint of strict originality, we consider that Fulton's work in the development of submarines and submarine mining was far superior to his work in the development of the steam boat, a fact which the letters published in this book and in various magazines of the past few months abundantly substantiate The book is a most valuable contribution to historical engineering literature.

The Printing Art Edited by Henry Lewis Johnson. Vol XIII. March, 1909—August, 1909 Cambridge Mass. The University Press, 1909 4to., 376 pp

The Printing Art is one of the most welcome visitors to the Editor's table, bringing as it does the very essence of good typography reproduced in concrete and useful form There is hardly a mechanical process which is not adequately represented in the beautiful volume before us. The Printing Art has done more for American typography than anything else which this century has produced so far Each number is filled with actual examples of properly printed illustrations and text. The latter is of the very best and the illustrations are largely taken from work which has been actually executed and is therefore of double value. In the bound volume before us all the advertisements including the cover are bound in This is a very wise precaution We do not see how anyone who is binding this beautiful publication would 'strip it' as a great deal of the practical value of the book is in the advertisements and inserts. There is no bad printer that this book will not improve and there is no good printer who cannot be assisted by it The printing art is young and the time is not far distant when the public taste will actually demand the very highest resources of plate making and printing, and this publication will go a long way toward furnishing a clearing house for the dissemination of fairly up-to-date ideas. We cannot comment too favorably on some of the examples of job printing particularly the programme title pages, many of which are superb. We shall preserve this volume for reference with a good deal of pleasure.

Sheet Metal Work By William Neubecker Chicago American School of Correspondence, 1909 Large 8vo, 270 pp, fully illustrated with diagrams. Price, $3

This is one of the best publications of the American Correspondence School that we have seen for some time The author is evidently a thoroughly practical workman but from his experience as a teacher has more facility for telling what he knows than most good workmen possess. His explanation of the methods adopted especially in laying out patterns is thoroughly practical and clear Just as much elementary descriptive geometry is included as is necessary for the understanding of the underlying principles, but no apprentice who desires to improve himself need be alarmed by that term if he knows nothing of the subject as it is given in a disguised and practical form on the lines of "reading without tears" Methods are given for the layout of every conceivable form of sheet metal from simple stove-pipe bends, joints and changes of diameter to the most ornate cornice work and we cannot imagine a workman being confronted with a problem to which he cannot find an analogy in this book. The form of the book is homologous as to printing and binding with the School's library and contains the usual foreword with no particular reference to this volume, but the diagrams are more than usually limited to those essential and applicable to the text.

Legal Notices

60 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO, 361 Broadway, New York
Branch Office, 625 F St, Washington, D C

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending October 19, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Abdominal supporter, E. F Small	937 724
Acid compound of alpha-lactic-anilid, making sulphurous, Stephan & Rahtjen	937,194
Addressing machine T. E. Plater	937,548
Adjusting mechanism, A. H Wouters	937 134
Advertising device, coin controlled, J H Montgomery	937,318
Aerator, L. B. Leach	937 169
Aerial navigation, J S. Letts	937,250
Aeroplane, D. S. Foster	937,587
Aeroplane motor driven A H. Moeller	937 351
Agricultural implement, M. Searles	937 156
Air brake system, G Macloskie	937 429
Airship, B. F Seymour	937 167
Alloy, Craft & Harris	937,294, 937,295
Annunciator and advertiser, street and station, Liversedge & Donnelly	937 253
Apparel cutting apparatus, M H. Kellogg	937 214
Apron or tube holder, sterm, C, S Beebe	937,222
Arm fitting apparatus, A. C. Freeman, Jr	937,589
Armor (tired wheel), C. E. Dulin	937,149
Auditorium seat, E. Wilson	937 181
Automobile, H. K. Holsman	937,311
Automobile brake, C. Todd	937,227
Automobile braking mechanism, H K Holsman	937,312
Automobile circular receptacle G V Haggerty	937 620
Automobile coupling, A. Keage	937,367
Automobile seat, detachable, Graves & Bennett	937,585
Awnings, cords or straps, locking device for, E. Asch	[illegible]
Axle, vehicle, D. E. Mosher	[illegible]
Axle vehicle, J V Huston	937,580
Back band and hook, adjustable iron G W Moores	937 287
Bait casting reel W T Bronson	937 672
Baking pan J F Costa	937 424
Baling press J Haag	937 138
Banana shipping case G W Hoffman	937 606
Barbers chairs head rest for R. S Wallace	937 343
Barber's comb, R J Sheffield	937 475
Barrow hand, W F F Nehls	937 682
Basins, tubs, and the like waste and overflow for C F Longfellow	937 079
Bath tub attachment H. M Shipp	937 470
Battery See Electric battery	
Bean picking machine G F Crippen	937 695
Bearing, ball O H Karcher	937 173
Bearing for cars, center J C Barber	937 088

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

CAPITAL WANTED.—I desire to take out letters patent in the principal countries in the world for a new type of dirigible balloon and an invention in aeroplanes which will rise perpendicular from the ground. Will give one-third interest to party who will furnish capital to patent. L. E. L. Thenke, Winnipeg, Can. (Gen. Del.)

Inquiry No. 8886. Wanted to buy nickeloid for butt ons.

WANTED.—Capital and business ability for combination clothes horse curtain stretcher, also safety gas burner. Will sell half interest in clothes horse for $1,000. New Inventions. Inventor Box 773, New York.

PATENTS FOR SALE

FOR SALE.—Patent No. 888,888. The most useful automobile appliance known. No auto stalled that has this appliance. Address H. S. Delamere, Room 1 South Berkeley Bank Building, Berkeley, Cal.

Inquiry No. 8960. For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

FOR SALE. Patent No. 863,178. Door knob to adjust to doors of various thicknesses. No small screws to loosen and drop out. Can be made cheap. Address J. T. Henderson, Box 24, Niagara Falls, Canada.

Inquiry No. 8918. For manufacturers of "Wyatt's Electro Catalytic Sparking Plug.

FOR SALE. Patent No. 926,141. Improvements on airships and air planes. For further information write to A. E. G. Lubke, 823 Clayton Street, San Francisco, Cal.

Inquiry No. 8929.—Wanted the address of Worthington Boiler Co.

FOR SALE. Patent No. 924,266. Electrolier switch controlling each lamp separately, step by step advancing movement, operated by a chain or similar means. Address Chas. Tomschik, 319 W. 51st St., New York.

Inquiry No. 8966.—Wanted the address of the Onbandet Motor Co.

OUTRIGHT SALE OR ON ROYALTY. U. S. Patent No. 886,827. Canadian Patent No. 118,852. An apparatus for producing uniform fluid pressure for engines. A great saving in expense. For further information write Elmer Engebretson, Devils Lake, North Dakota.

FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 8 to 40 in. Price only $45.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 8987. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 8996. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

Inquiry No. 9010. Wanted to buy a "Rector Help-a-Phone."

Inquiry No. 9012. Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

Inquiry No. 9014.—For manufacturers of machinery supplies etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

Inquiry No. 9016.—Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

Inquiry No. 9018. Wanted, the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9022. Wanted to buy a light, small motor not exceeding three pounds in weight, including everything in going order.

Inquiry No. 9023. Wanted, to buy silk machines from re reeling twisting doubling to the final process of making it into clothes.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Inquiry No. 9026. Wanted, address of parties who make "invar" or other metals having a low coefficient of expansion.

Inquiry No. 9027. Wanted, the address of manufacturers of small wooden articles.

Inquiry No. 9028.—Wanted, to buy a washing machine that is run by a coil spring motor.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9030. Wanted the address of firms manufacturing a wood fiber bottle and case made from same material.

Inquiry No. 9032. Wanted the address of parties who supply carriage and wagon makers with white gum wood blocks for making hubs for vehicle wheels.

Inquiry No. 9034. For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9035.—Wanted manufacturers to make a metallic case somewhat similar to the "Thermos" bottle.

Inquiry No. 9036.—Wanted the address of the manufacturers of "Cycle Ball Bearing Suspenders."

RUBBER STAMP MAKING.—THIS article describes a simple method of making rubber stamps with inexpensive apparatus. A thoroughly practical article written by an amateur who has had experience in rubber stamp making. One illustration. Contained in SUPPLEMENT 1110. Price 10 cents. For sale by Munn & Co., Inc. and all newsdealers.

will instruct personally a limited number ambitious men in

Practical Drafting, Detailing, Designing

I know exactly the quality and quantity of practical training, knowledge and up-to-date experience you require to hold a position and advance to highest salary, and I give working instructions at home until competent and placed you in position. Address CHIEF DRAFTSMAN, Div 24 Engineer's Equipment Company (Inc.) Chicago, Ill.

How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT 1615, A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr. Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

MUNN & CO., Inc., 361 Broadway, New York

THIS GRINDER

Has no pumps, no valves. No piping required to supply it with water. Always ready for use. Simplest in construction, most efficient in operation. Price will interest you.

W. F. & JNO. BARNES CO.,

Established 1872

1999 Ruby St., Rockford, Ill.

Concrete Reinforced Concrete —AND— Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete, by Brysson Cunningham. The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1586 gives the proportion of gravel and sand to be used in concrete.

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J. Jones of the various systems of reinforcing concrete, concrete construction and their applications. These articles constitute a splendid text book on the subject of reinforced concrete. Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry.

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A. Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H. Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley, Jr., on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete, depositing of concrete, facing concrete, wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

SPARK COILS
Their Construction Simply Explained

Scientific American Supplement 160 describes the making of a 1½-inch spark coil and condenser.

Scientific American Supplement 1514 tells you how to make a coil for gas-engine ignition.

Scientific American Supplement 1522 explains fully the construction of a jump-spark coil and condenser for gas-engine ignition.

Scientific American Supplement 1124 describes the construction of a 6-inch spark coil.

Scientific American Supplement 1087 gives a full account of the making of an alternating current coil giving a 5-inch spark.

Scientific American Supplement 1527 describes a 4-inch spark coil and condenser.

Scientific American Supplement 1402 gives data for the construction of coils of a definite length of spark.

The above-mentioned set of seven papers will be supplied for 70 cents.

Any single copy will be mailed for 10 cts.

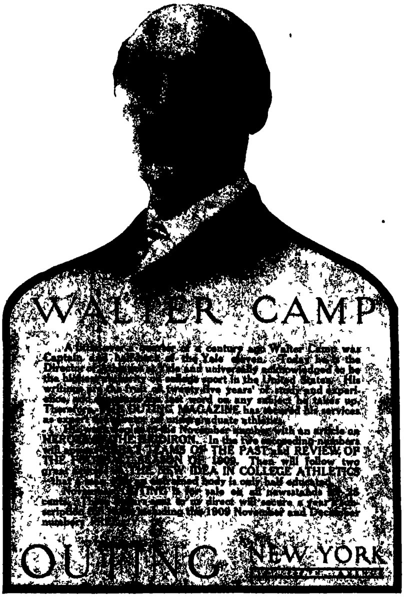
A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.



WALTER CAMP

A [illegible] quarter of a century ago Walter Camp was Captain and [illegible] of the Yale eleven. Today he is the Director of [illegible] at Yale and universally acknowledged to be the highest authority on college sport in the United States. His writings are the fruit of twenty-five years' of study and experience, and [illegible] the last word on any subject he takes up. Therefore THE OUTING MAGAZINE has secured his services as expert [illegible] on undergraduate athletics.

He [illegible] the November number with an article on HEROES OF THE GRIDIRON. In the two succeeding numbers will appear [illegible] TEAMS OF THE PAST and REVIEW OF THE FOOTBALL SEASON OF 1909. Then will follow two great articles on THE NEW IDEA IN COLLEGE ATHLETICS —that [illegible] body is only half educated.

November OUTING is for sale on all newsstands at 25 cents. [illegible] sent to us direct will secure a year's subscription [illegible] including the 1909 November and December numbers.

OUTING NEW YORK

Copyright, 1909, by Munn & Co Inc.

The Middle West Number of the **SCIENTIFIC AMERICAN**

On December 11th 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West in part at least, into a manufacturing territory

With that object in view the Middle West Number will publish articles on the following subjects

I. The Chicago and Gulf Waterway.—An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II. Chicago as a Railroad Center.—Chicago is the greatest railroad center in the world

III. The Wonderful Grain Trade of Chicago —Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured.

IV. Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of 10,000 and 12,000 tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. Freighting on the Mississippi.—Freighting on the Mississippi is a more important industry than most of us may realize

VII. The Steel Industry.—One of the greatest steel plants in the world is that which has been built at Gary

VIII. The Freight Subway System of Chicago. Chicago can boast of a rational system of handling freight by means of subways.

IX. The Water Supply of Chicago.—Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X. Reclaiming Arid Lands.—The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered

XI. Harvesting the Grain of the Middle West. Farms that cover not acres but square miles, crops that aggregate not simply bushels but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West. The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated.

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN It will be lavishly illustrated It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

THE AMERICA'S CUP

Securely locked away in some safe deposit vault in this city is a curious old silver cup which shows in the fantastic crudity of its design all the earmarks of that Victorian age in which it was fashioned. Its cash value is stated to be five hundred dollars, which may be taken to be its probable value if melted up for the silver that is in it. Of no worth as an object of art, the cup is to-day probably the best known, as it was once the most eagerly sought-after prize in the world of international sport. Won over half a century ago by the epoch-making schooner "America," it has been the object of most strenuous competition and has caused the expenditure of millions of dollars by yachtsmen on both sides of the Atlantic. With a persistency which is characteristic of the race, the British have sailed yacht after yacht over the ocean, in the hope of taking the "America's" cup back to English waters and transferring the scene of future contests to those shores off which the "America" won her famous victory.

The effect of the "America" cup contests on the development of the sailing yacht, particularly in the later years, has been to produce a craft of such extreme proportions—vast sail spread, fragile hull and spars, and excessive draft—as to render her useless for ordinary cruising and fit only for the marine "graveyard" and the junk pile. Truly a most amazing statement, but fully guaranteed by the fact that during the past decade no less than six challengers and defenders for the cup, costing altogether probably not less than a million and a half dollars, have been broken up and sold for old metal.

As far as the records of this half century of contests go, they have consisted of an unbroken string of victories for the American yacht, and the British must get what consolation they can out of the fact that the American designers, in their efforts to hold the cup, have had to forego the characteristic centerboard hull and sloop rig and come over to the English deep-keel and the cutter rig. The successive defeats of recent years have convinced the English yacht designers that they must abandon all hope of outbuilding and outsailing the American defending yacht, so long at least as there is no restriction upon lightness of hull and size of sail spread.

Some years ago our own yachtsmen and those of France, Germany, and England came to the conclusion that the time was ripe for making such changes in the rules of measurement as would modify, or control, those extremes of construction which have rendered the racing yacht an unseaworthy, unwieldy and outrageously expensive craft to build and maintain in commission. Both here and abroad new rules have been adopted, which have resulted in the production of yachts that are in average weather as fast as the "freak" boats, and at the same time are suited for the average summer cruising. Sir Thomas Lipton, the most persistent of all contestants for the "America's" cup, has been told by the English designers that they are unable to build a yacht under the old rule for which they can give an assurance of any likelihood of success in the contests off Sandy Hook. They claim that a boat built of sufficient staunchness to take the chances of a stormy Atlantic crossing cannot compete with a craft which during her season's sailing never has to venture out of sight of land, and does most of her racing in the sheltered waters of Long Island Sound and within a few hours' sail of the yard in which she was built. To this the reply has been made that, since the English yacht is towed across, carrying a reduced rig, the danger of her foundering in heavy weather is eliminated.

The writer once put it squarely to Mr. William Fife, designer of two of the challengers, whether he considered the ocean crossing to be a handicap. After a few moments' thought he replied: "Theoretically, no, but actually, yes, and this for the reason that, however keen a yacht designer may be in his desire to cut down weights, his humanitarian instincts will remind him that the lives of over a score of men are to be committed to that shell, to take the chances of a three weeks' crossing of the Atlantic." Be that as it may, the fact remains that the British have frankly acknowledged themselves beaten, under the present rules, in contests between yachts of unrestricted lightness, and Sir Thomas Lipton is in our midst to-day requesting that the New York Yacht Club sanction an "America" cup contest under their own new rule, under which for some years their regattas have been held.

The New York Yacht Club contends that, since the "America" cup stands for the fastest yacht that can be built, and since it has been proved that the fastest yacht can be built under the old rule, therefore for "America" cup contests the old rule is the proper one to sail under—and there can be no doubt that technically the attitude of the Club is correct. At the same time, we believe that under the present Deed of Gift the challengers and defenders may mutually agree to make certain changes in conditions if they so wish. All the same, we would suggest that, since racing for the "America" cup under existing conditions is at an end, and since, after all, the cup is merely an emblem of the sport, and it is the sport and not the cup that is the ultimate object of yacht racing, it might be as well to make a sufficient modification of the old rule to encourage the yachtsman, not merely of Great Britain but of that other great yachting nation, Germany, to make a try for the famous old trophy.

DOVER'S GREAT ARTIFICIAL HARBOR.

The opening of Dover naval port marks the completion of the greatest artificial harbor ever built entirely in the open sea. The scheme includes an extension of the Admiralty pier for two thousand feet, the formation of reclamation works for the protection of the shore at the eastern end of Dover town, extending in the direction of St. Margaret's Bay for three thousand nine hundred feet, a protecting arm extending from the eastern end of the reclamation for a distance of two thousand nine hundred feet into the open sea, and an island breakwater approximately parallel with the shore line and extending from the end of the Admiralty pier extension on the west to the end of the easterly pier already referred to, with wide entrance openings between the heads of the several breakwaters. If we include the eighty acres which constitute the present commercial harbor, there is inclosed by these works a total area at low water of six hundred and ninety acres of deep-water harbor, capable of floating the largest of modern battleships and ocean liners. This is the largest area of the open sea ever inclosed by solid masonry protecting works.

Although that portion of the inclosing breakwaters which is visible at high water gives an impression of their great length and of the wide extent of the harbor, it is a fact that the visible masonry represents only a small proportion of the work actually done. The total length of the sea works is two and a half miles, two miles of which are in exceptionally deep water. Thus, the two-thousand-foot extension of the Admiralty pier measures from the top of the parapet to the foundation nearly one hundred feet in height, and the eastern pier has a total height above foundations of eighty-seven feet. The total width at the base of the piers is over fifty feet and at the top forty-seven feet six inches.

It is an interesting historical fact that it was Sir Walter Raleigh who first drew attention to the strategical and commercial importance of Dover, speaking of it as "situated on a promontory next fronting a puissant foreign king and in the very straight passage and intercourse of almost all the shipping in Christendom." It was as far back as the year 1840 that a Royal Commission recommended a scheme of harbor construction at a cost of ten million dollars. Out of the deliberations of this and subsequent commissions came the decision to construct the Admiralty Pier, so well known to Americans who visit or return from the Continent by way of England, for which a contract was let in 1847, but which did not reach completion until twenty years later. It was not until the year 1895 that the plans for the present fine harbor took definite shape, the contract was let in 1897, and active construction commenced shortly afterward. The fears which have been expressed that this, like other harbors won from the open sea, might be subjected to shoaling up by drifting sands have not been verified, the depth remaining practically constant.

IMPROVEMENTS IN NEW YORK'S HIGH-PRESSURE FIRE SERVICE.

A recent order of the New York Fire Department relieves the fire engines of the various companies in the district protected by the high-pressure water service from responding to alarms of fires, and may be considered as a practical and official indorsement of the complete success of the system. Soon after the high-pressure was installed the right of way in going to a fire was given to the hose wagons over the engines, and while the latter answered alarms they were held in reserve or used merely for washing down after the high-pressure lines had extinguished the fire.

The successful and intelligent use of the high-pressure by the Fire Department was accompanied by a careful study of the actual workings of the system by the engineers of the water department with a view to detecting any possible defects. As a result the new extension, now beginning to be installed and aggregating some twenty-one miles of mains, represents a marked improvement over the part at present in use, which, as the largest and most complete plant of the kind, is serving as a model for other cities. The most important improvement is a duplicate arrangement of mains so that in case of a break or other failure one-half of the system can be cut out immediately without impairing the efficiency of the other half in any way. This is secured by gridironing the territory with two independent systems whose mains are laid in alternate streets. Thus in the case of a break in a main supplying a hydrant on a certain street, that half of the system to which it belongs can be shut off at once and the firemen only have to stretch their hose from a hydrant connected with the other set of mains, usually to be found on the next street. The two systems and their hydrants, which will probably be painted a different color or otherwise marked, are so arranged that a hydrant of the second system is never over 500 feet from any given point, just as under normal working conditions there is a hydrant within at least 200 feet of any possible fire.

The desirability of such an arrangement was apparent to the water department engineers at a fire on December 16th, 1908, at Grand and Mulberry Streets, when the high pressure service had its only failure and was temporarily out of service. This was due to a break caused by the giving way of a temporary end of a main in an excavation for the Centre Street subway, where the supports for the main had been cut away by the subway contractors.

While it is possible to locate and cut out any section where a break occurs by means of valves located at street intersections, yet this process may require considerable valuable time when the water is seriously needed at the fire. The valves themselves are ponderous affairs moved by hand, and to close the two, three, or four required to cut out a broken section may consume from twenty minutes to half an hour. Accordingly after studies by the engineering staff of the high pressure division of the water department it was decided to install an independent system of two mains as outlined.

Normally, both systems will intercommunicate and connect with the present system so that there will be a complete circulation of water, supplied at any desired pressure from the pumping stations at Gansevoort and West Streets and at Oliver Street and East River. Now, in case of a sudden break the gage at the Oliver Street station connected with the outlet of the half of the system involved will be immediately apparent and that portion can be shut off at the station. This is accomplished by closing the appropriate valves on the outlets at the station and two distant controlled valves at the Bowery and Houston Street or at New Chambers and Cherry Streets, depending on the part involved. All of these valves are electrically worked and can be operated simultaneously so that one system or the other can be isolated in less than a minute. This increased measure of safety, the importance of which cannot be overestimated, is rendered desirable not through any inherent defect in the high-pressure system but largely on account of the conditions under which it must be installed and operated in a city like New York, where frequent excavations and gas explosions are likely to damage the mains or produce weakness that only service conditions may develop. If the break is detected in season it is of course possible to isolate the crippled section and notify the firemen accordingly, but failure in service is a serious matter which the new duplex system will render much less dangerous.

Few pieces of municipal engineering have been better planned, constructed and operated than New York's high-pressure service, and that it is capable of still further improvement would indicate that, when this form of fire protection is provided for the entire city, it will eliminate the possibility of a large conflagration, which Chief Croker states is no longer to be feared in their present protected district. Further extensions besides the one under way are contemplated in the near future, and additional pumps will be installed.

[illegible] the Railway [illegible] job of excavation [illegible] than 37,172,654 cubic [illegible] one-half of the total excavation, had [illegible]. The grand total for September was [illegible] cubic yards, which is 1,042,852 cubic yards less than the highest record, which was made in March, 1908.

The State Department has been informed that the President of Guatemala has directed a bronze bust of Robert Fulton to be placed in Estrada Cabrera Park in Guatemala city in recognition of Fulton's genius. The government of the United States has directed the American Minister at Guatemala city to express its appreciation to the Guatemalan government for the honor thus done to the memory of a distinguished American.

The Commissioner of Patents has decided in favor of Commander Cleland Davis, U. S. N., in the interference proceedings that have been pending for many months past against his application for patent on his projectile-carrying torpedo. One witness testified that in the spring of 1903 Davis drew a diagram of his device upon a napkin and explained that his idea was to insert in a torpedo a gun which would discharge a high explosive shell through the armored bottom of a ship and enable it to explode within the vessel.

The inauguration of railway travel through the tubes of the Pennsylvania Railroad Company between New Jersey and Long Island took place recently without any demonstration and under very prosaic conditions. The first trip was made by a train of dump cars hauled by an ordinary switch engine, which passed from Jersey City beneath the North River, Manhattan Island and the East River to Long Island City The formal opening of this great work will probably take place within the next few months.

According to a dispatch from Quebec, the Harland & Wolff shipbuilding firm of Belfast, Ireland, working in conjunction with the Canadian Pacific Railway, have acquired a large area of land at Levis, at which dry-dock, ship repairing, and building plants will be built this spring for the purpose of building Canada's navy. Sir Thomas Shaughnessy, president of the Canadian Pacific Railway, refuses to discuss the rumor It is said that he personally conducted the negotiations between the shipbuilders and the government.

The largest scrap heap in the world is in San Francisco, a relic of the great fire which followed the earthquake of April, 1906. It is 40 feet high, 100 feet square and contains 20,000 tons, all cut in equal lengths of eighteen inches, and piled in one solid mass, with the sides as plumb and true as a brick wall This is the only one of four heaps of equal size and proportions which remains intact in its original size and shape, the other three having been drawn upon as the material was needed.

An extraordinary accident happened at Durban, South Africa, to an immense traveling coal unloader, mounted on four trucks and traveling on two pairs of standard-gage rails 80 feet apart, which can pick up and dump an ordinary railroad car full of coal. It was blown along the track by a gale until it left the metals, when in spite of the stability due to its large wheel base as compared with its height, it fell over on its side. As it has booms 190 feet long, and is nearly 100 feet high, the task of re-erecting it calls for considerable ingenuity

That the submarine bell is valuable in preventing delay of ocean liners by fog has recently been proved in the case of the "Lucania" and the "Kaiser Wilhelm der Grosse." The former vessel, while approaching New York, was enabled to make the light vessel by submarine bell signals, these being her sole guide The captain of the "Kaiser Wilhelm der Grosse" when on his eastern passage was shut in by dense fog near Fire Island light vessel. He was able to hear the submarine bell and direct his course accordingly, although, as it subsequently transpired, he was twelve nautical miles distant from the signal station. It is significant that at the same time the fog horn of the lightship was quite inaudible.

A breakwater which, when completed, will be some 10,000 feet in length, is now in course of construction at Hilo, in the Island of Hawaii, to protect shipping from the heavy seas that sweep from the northeast. At present some 400 feet have been completed, and under the existing contract it is estimated that by the middle of next year a length of some 3,000 feet will be in position. The material used for construction is a basalt rock resembling heavy granite, which is quarried some 15 miles away, and transported to the works under contract with the Hilo Railway Company According to the specifications, from a depth of 3 feet below the water-line to the top, boulders of not less than 8 tons in weight are to be used. The contractors [illegible] that the work is [illegible] which weighs [illegible] without the use of cement, [illegible]

ELECTRICITY.

The chief engineer of the British Post Office Department, Major Walter O'Meara, is visiting this country for the purpose of studying our telephone systems. The British government is to take charge of the entire telephone system of Great Britain in 1911. It will be operated as is the telegraph system, by the Post Office Department.

The contract has just been let for the huge dam across the Conchos River in Mexico. This dam will form a reservoir of 1,840,000,000 cubic meters capacity. The hydro-electric plant which will obtain power from this source has a capacity of 25,000 horse-power, which will be used at a number of large mines within two hundred miles of the generating station.

An electric railway has just been completed running from Ville Franche to Bourg-Madame The line is thirty-four miles long and it has a schedule of three trains a day in each direction. Starting from Ville Franche at 1,407 feet above the sea the line rises to 5,220 feet and then drops to 3,750 feet at Bourg Madame. The motor cars are each equipped with four 50-horse-power motors. The third rail system is used and energy is supplied at about 800 volts.

A circular has just been issued by the Bureau of Standards discussing electrical measuring instruments in general, describing the various types of instruments, pointing to the sources of error and explaining methods of checking them. The Bureau undertakes to test any instruments sent to it for this purpose, making a small charge for the work involved The circular contains the regulations governing these tests, and a schedule of the fees charged

The city of Liverpool is at present experimenting with flaming arcs and tungsten lamps for street lighting. A row of flaming arcs is set on posts in the middle of one of the principal streets The arcs are 20 feet above the ground, and 10 feet below each is a circle of 25-watt tungsten lamps. At midnight the arc lamps are extinguished and the filament lamps are used in place of them. On one of the narrower streets clusters of tungsten lamps are hung over the center of the street from wires strung across from the buildings at opposite sides, thus avoiding the use of poles

A series of lectures has been given before the Fire Insurance Club of Chicago by Mr B E. Blanchard, who is the Chief Electrical Inspector of the Chicago Board of Underwriters. The subjects so far discussed are "Electricity," "The Electrical Inspector" "Outside Work—Systems and Voltages," and "Inside Work' The remaining two lectures will deal with 'Low Potential Systems" and "High Potential Systems" These lectures have been found very instructive because the subjects are explained in simple non technical language, so that the insurance men readily understand them

The Committee on Units and Symbols of the German Association of Electrical Engineers has just published a report suggesting uniform symbols for alternating-current units. There has been some criticism of these recommendations, because the letters used represent German words and differ materially from the symbols common in other countries. While standardizing of symbols is to be highly recommended, it is pointed out that the symbols should be such that they may be adopted by other countries as well so that eventually we can have an international set of standard symbols and thus avoid some of the confusion that now exists in electrical literature

Evidently carbon filament lamps are still receiving considerable attention in England. Two patents have recently been issued on the subject, one aiming to regenerate the filament, and the other to prevent the blackening of the glass bulb. In the first case the bulb is opened, and after being cleaned hydrocarbon is introduced. Then on heating the lamp the hydrocarbon is decomposed and the carbon is deposited on the filament. In the second case the inventor believes that the blackening of the glass may be obviated by removing the mercury vapor which enters therein while the bulb is being evacuated. Therefore he proposes to coat the stem which holds the filament with silver, so as to absorb the mercury vapor

A recent article in the Electrical World contains the following data relative to the utilization of the energy from Niagara Falls. Of the 5,000,000 horse-power represented by Niagara Falls, only about 5 5 per cent is being utilized. Of this, 126,800 horse-power is employed in electro-chemical processes, 56,200 horse-power for railway service, 26,400 horse-power for lighting, 45,840 horse-power for various industrial services, 12,200 horse-power is transmitted over more than one hundred miles, 31,565 horse-power between seventy-five miles and one hundred miles, 3,100 horse-power fifty miles, 78,840 horse-power between ten and thirty miles, while 145,400 horse-power is used locally, showing that many industries have been attracted to Niagara Falls because of the favorable electric power conditions to be found there.

SCIENCE.

Halley's comet appears to be growing brighter somewhat rapidly It was seen without difficulty at Harvard on October 17th by Prof. Wendell with the 15-inch equatorial, and by Mr L. Campbell with the 24-inch reflector

Leon Guillet's and Ch. Griffiths's experiments on the cementation of iron by pure carbon show there is no cementation if precautions are taken to prevent the presence of gases, but it takes place if contact is insured Moreover, it increases with the pressure, but always occurs extremely slowly

The American Machinist states that the methods of race-track gamblers, who dope horses in order to make them win races, have been copied by unscrupulous owners of gasoline racing boats The gasoline is doped with picric acid or some other high explosive, and with the increased power thus obtained the boats are able to win races they would lose if ordinary straight gasoline were used On the race track there are stories of plugs which have been overdoped and died and it is said there are also gasoline engines which have been unable to withstand an overdose of picric acid and have gone heavenward

Samples of air at a height of nearly nine miles have been recently obtained and examined for the presence of the rare gases. The collecting apparatus, carried by a large balloon is a series of vacuum tubes each drawn out to a fine point at one end At the desired height an electro-magnetic device, connected with each tube and operated by a barometer, breaks off the point of the tube admitting the air A few minutes later a second contact sends a current through a platinum wire around the broken end, melting the glass and sealing the tube All the samples obtained show argon and neon but no helium was found in air from above six miles

A 40-inch mirror is almost completed by Clark for Prof Percival Lowell at Flagstaff, Arizona. The mirror is to be thicker than usual to avoid flexure and is to have a focal length of 18 feet 4 inches. A series of zinc blocks between the iron supporting ring and the edge of the mirror avoid strains on the glass with changes of temperature When arranged for planetary work, secondary mirrors are to be provided which will transform the instrument into a Cassegrainian reflector of either 154 feet or 75 feet focal length. For photographing nebulæ and stars a plane mirror will be used as secondary giving the images at the principal focus

Harvard College Observatory issues a bulletin stating that Prof E E Barnard of the Yerkes Observatory obtained visual observations of Halley's comet on the 17th and 19th of October On these two dates Prof Barnard found that the comet was not fainter than the 13¼ magnitude, having a diameter of 15 seconds, and while it exhibited no elongation, it was 'less indefinite and brightening in the middle" In summarizing the late European observations of Halley's comet Nature points out that the date of the comet's perihelion passage must be advanced 3 4 days, thereby making it April 20, 1910 The comet is at present distant about two hundred and eighty million miles from the sun and two hundred and thirty million miles from the earth

A French investigator M de Wegrier recently described an apparatus designed to prevent the formation of hail. A similar apparatus was invented by Beckensteiner fifty years ago and was described under the name 'géomagnetifére" in his Etude sur l Electricite' To the top of a pole about 65 feet high made of the trunk of a resinous tree and painted with oil in order to make it a non-conductor was attached a mass of gilded copper with five points connected to earth by a magnetized (?) galvanized iron wire The apparatus also included a large metallic net or grating, buried in the earth Dr Frestier has repeated and extended Beckensteiner's experiments and has obtained conclusive proof of the efficacy of the apparatus as a preventive of hail

The method of forcing plants by treatment with ether, as first suggested by Johannsen is now extensively used on a commercial scale for the purpose of securing out-of-season flowers and fruit This process, however, will in all probability soon be replaced by the equally effective and less expensive method just described by Prof Molisch in a pamphlet called "Das Warmbad" The only treatment required is that of immersing the shoots, by inversion, in water at 30 to 35 deg. C, for nine or twelve hours, and afterward keeping the plants in a dark moist chamber at a temperature of about 25 deg. until the leaves commence to appear, after which the plants are grown under ordinary greenhouse conditions. Lilacs, azaleas spiræas, etc, treated as above during the middle of November were in bloom at Christmas or early in January, whereas untreated plants of the same kind had not commenced to move. Fuller methods of treatment and the duration and temperature of the bath for different kinds of plants, are contained in the pamphlet.

A REMARKABLE MEXICAN CONCRETE CONDUIT AT GUADALAJARA.

BY FRANK C. PERKINS.

In the Rio San Juan Ravine, which passes through the heart of the city of Guadalajara in Mexico, a circular concrete conduit has been constructed to serve as a storm water drain. This reinforced concrete conduit is of novel construction; and on account of its design and size is of special interest. It is somewhat over 13 feet in diameter and is circular in form for most of its length, the upstream section, however being flattened in order to avoid a large amount of excavation in rock.

This Mexican concrete conduit is nearly a mile in length. It passes to one side of the center of the city for about a mile, and drains nearly 17,000 acres. It has a grade of 4 feet per thousand feet, and has a thickness of 10 inches of concrete, reinforced by double rings or round corrugated bars. These bars are placed one foot apart longitudinally, in two circles, the inner and outer bars alternately The bars each measure one-half inch in diameter

It is stated that the total concrete in the conduit measures 13 000 cubic yards, the steel used for reinforcing weighing 300 000 pounds. In the construction of this conduit, 40 per cent of river sand was utilized and 60 per cent of sand made from crushed rock. Three parts of this sand are used with three of crushed rock and one of cement, the latter being of the Hidalgo brand, made at Monterey, Nuevo Leon, which is said to be about the only factory producing Portland cement in Mexico.

One of the accompanying illustrations shows a portion of the completed conduit and the moving of the high exterior forms by means of traveling gallows frames. This system of molds and the apparatus for shifting them is simple and very efficient.

Other illustrations show the erecting of forms inside of the reinforcement which is supported on concrete blocks, as well as the method of placing the reinforcing bars in position There was a test made of the strength of the conduit about 25 feet in length when a week old by passing a roller weighing 32,000 pounds over it, and also by allowing the roller to stand upon it for 120 minutes After this severe test it was found that no crack developed, the earth filling over the top of the conduit in the test being about three feet in depth

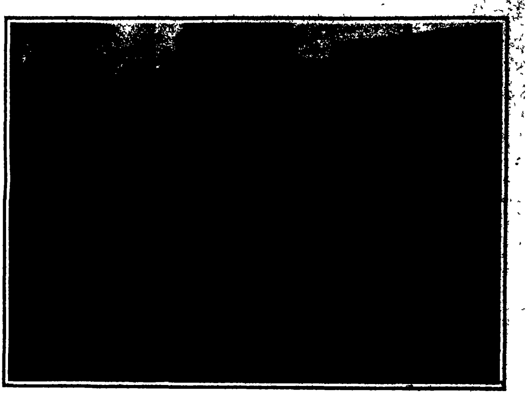
Cultivation of Edible Fungi in Forests.

In many districts of Perigord in southern France, the black truffle (*Tuber melanosporum*), the most highly-prized species is artificially propagated For this purpose the tubers are dried, cut into small pieces, mixed with water, and ground to a thin paste, small quantities of which are spread upon green hasel or oak leaves, which are buried in the earth under oak trees. The first truffles appear five or six years afterward. In Germany the black truffle is found only in the west The truffles which grow in central Germany are of inferior species, hence Prof Mayr recommends the artificial propagation of black truffles, according to the Perigord system, in the warmer parts of Germany, especially where oaks abound, as the production of truffles is dependent upon the presence of deciduous and particularly of oak forests. The mushroom also grows well in the forest, but its artificial culture is usually carried on elsewhere Experiments made by Mayr for the purpose of colonising the mushroom in localities in the forest where it does not grow naturally have met with no success, although they have been continued for five years. The attempt at colonising was made by taking up the mushrooms immediately before the ripening of the spores, and transplanting them to the desired spot, on which the spores necessarily fell. On the other hand, Schroeder, in a recent article, has described his success in transplanting the craterelle (*Craterellus nucleatus*) which in flavor is surpassed only by the Perigord truffle. Selected spots in the forest planted with spores of this fungus bore abundantly

In Japan, Mayr has had opportunity to observe the artificial propagation of the most delicious of all Japanese fungi, the *Agaricus shitake*. The cultivation of this fungus is the only form of forestry practised in extensive districts in Japan Young trees of various deciduous species, or boughs as big as a man's arm or leg, are cut immediately after the fall of the leaf, allowed to lie about one hundred days in the forest, and then sawn into logs three or four feet long, in which deep incisions are made The spores of the fungus, which are present everywhere in these districts, penetrate the incisions, and develop a mycelium which [illegible] The mushrooms [illegible] the logs in the following autumn, and [illegible] abundantly from the second to the fifth year, [illegible] both from the incisions and from the [illegible]. Mayr has recommended the cultivation of the Japanese mushroom in Germany, and has made experiments by inserting bits of mushroom-bearing wood, brought from Japan, into holes bored in boughs cut from deciduous trees. The experiments proved that the beech, the hornbeam, and the birch are best suited for the culture of the fungus, but that the young cultures are greatly injured by snails, and also by the competition of native fungi.—Prometheus.



How the reinforcing members are placed in position.

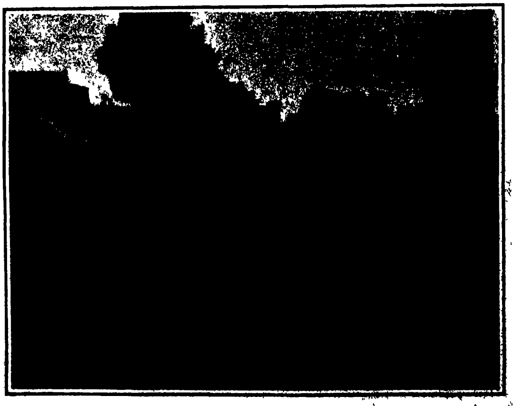
Ammonia from Atmospheric Nitrogen.

A new process for producing ammonia from atmospheric nitrogen has been developed from experiments in the synthesis of hydrocyanic acid, which were made by Walterreck and Eschweiler, of Hanover.

In these experiments, in which a dry mixture of hydrogen and nitrogen was passed over iron at a dull red heat (about 900 deg. F), a small quantity of ammonia was always formed. This result was subsequently confirmed by Sir William Ramsay Ammonia was formed only at the beginning of the reaction, but it was found that larger quantities of ammonia could be obtained by passing a mixture of air and coal gas over oxide of iron, and this result led to a series of experiments with various oxides of nickel, cobalt, copper, cadmium, silver, lead, bismuth, chromium, and iron. The most interesting results were obtained with oxides of bismuth, chromium, and iron. The oxide was inclosed at first in an ordinary combustion tube, afterward in an iron tube. The mixture of equal volumes of air and coal gas was moistened by passing through distilled water heated to [illegible] deg. F, as a certain quantity of moisture was found advantageous. The yield of ammonia varied greatly with the temperature, the best results being obtained between 570 and 660 deg. F

It was observed, however, that the production of ammonia diminished as the oxidation of the iron increased, so that it was necessary to reduce the iron from time to time by passing hydrogen or carbon monoxide through the tube at a high temperature.

Experiments were then made for the purpose of finding some other sufficiently cheap substance, the oxidation of which would produce the same result, without requiring repeated reduction. Coke, wood charcoal, peat, and lignite were found to satisfy these requirements fairly well. With coke the process is very slow; much more satisfactory results are obtained with peat. One specimen of peat, containing [illegible] per cent of water and little more than 1 per cent of nitrogen, furnished 8 per cent by weight of sulphate of ammonia. In a large number of experiments made with a horizontal iron retort, such as used in the analysis of coal, [illegible] per cent of sulphate of ammonia was obtained. As this was more than the nitrogen of the peat would furnish, it was inferred that part of it must have been derived from the nitrogen of the air. This conclusion was confirmed by experiments with [illegible] which contained no nitrogen. In the [illegible] peat and other forms of carbon [illegible]



Part of the completed conduit.

A REMARKABLE MEXICAN CONCRETE CONDUIT AT GUADALAJARA.

[illegible] IN MILWAUKEE.

The scene of [illegible] destruction depicted in the two accompanying engravings might well be supposed to represent the effects of the detonation of a large amount of high explosive so complete is the demolition of the building and so thoroughly have its contents been disrupted and scattered As a matter of fact the damage was entirely due to the explosion of a single boiler

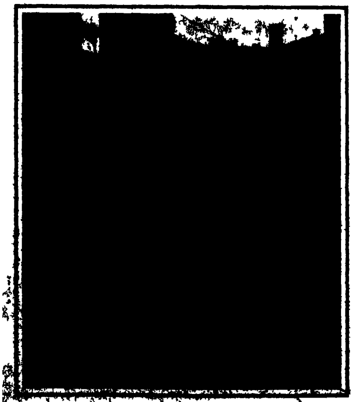
At first sight it would seem impossible that the amount of steam contained in a boiler at the instant of explosion should be sufficient to work the seemingly disproportionate amount of damage that generally ensues—disproportionate, that is to say in the wide extent and violent effects produced as compared with the cause Everyone who is familiar with boiler firing knows how quickly the reserve of steam in the boiler is used up in the cylinders of the engine if the firing be not faithfully attended to

The explanation of the great damage resulting from an explosion is to be found in the fact that the boiling point of water varies with the temperature and the pressure to which it is subjected If the pressure be suddenly reduced a rapid ebullition of the water ensues with the emission of great volumes of steam Consequently when the whole of the pressure upon the highly heated water in a boiler is suddenly removed by the rupture of the boiler shell the whole mass flashes at once into steam with a practically explosive effect which shows itself in the lifting of roofs the blowing out of walls and the hurling as is frequently the case of the shell of the boiler to distances of several hundred yards

The boiler which exploded was one of four which were erected in one of the boiler houses at the Pabst Works Milwaukee Wis The most sensational result—the one which gives a vivid idea of the energy of the expanding steam—was the fact that a big malt elevator 60 feet high adjacent to the boiler plant was moved four feet from its foundation This effect will be noticed by examining one of the accompanying engravings in which it can be seen that the remaining portions of the wall although they are strictly parallel with each other are out of line by about the four feet which it is estimated that the building was moved

The wall of a machine shop lying to the north was blown in Every window in this machine shop and most of the glass in the buildings surrounding the plant were broken as was most of the glass in stores and houses within a radius of two blocks of the explosion Tenth Street adjoining the building was buried under tons of debris which in some places was piled to a height of from six to eight feet Flues boiler pipes and various fragments of the boiler were scattered over the street and some of them were curled up into fantastic forms

It frequently happens in a boiler explosion particularly if one end be torn off and the main body of the boiler be left intact that the water flashing suddenly into steam and rushing out through the unclosed end reacts against the air with a violent rocket like effect and the mass of the boiler is driven to great distances In the present case a large section of the boiler went hurtling through the air across Tenth Street and fell upon the roof of a storehouse sixty feet in height where it remained imbedded Strange to say a lofty brick chimney over two hundred feet high, which formed a part of the plant and stood over the rear portion of the boiler room received not the slightest damage



[illegible] left is seen the wall of the building 60 feet high which [illegible] a distance of 4 feet.

The debris covered this street to a depth of several feet. A large portion of the boiler was thrown across the street and landed on a roof of a 60-foot building.

SOME PRINCIPLES OF BALL BEARING DESIGN

BY J F SPRINGER

The old but constantly recurring question as to whether the top of a wagon wheel actually moves faster than the bottom is really involved in the ball bearing problem There is one fundamental fact implied in all questions of rolling which when once thoroughly mastered will have great effect in clearing up dark places In rolling there is a progressive contact of one body with another of such character that there is no sliding That is to say at the point of contact there is absolutely no movement of the one body past the other In Fig 1 the wheel is rolling upon the ground *G* in the direction *C* At the present moment the point of contact is *A* If the motion is a rolling one then at the point *A* there is no slip or slide This means that the point of the wheel touching the ground at *A* has absolutely no motion But this point on the tire of the wheel enjoys this absolute rest for the instant only The next infinitesimal portion of time there is a different particle absolutely at rest And so on as the wheel rolls along every point of the circumference in succession becomes for one instant only an absolutely quiescent point What is moving is the position of the point of rest

This is true whether the rolling body rolls along a straight line or not If the line rolled upon however has any motion of its own then the contacting

SOME PRINCIPLES OF BALL-BEARING DESIGN

point of the rolling body is at rest only with reference to this moving line. As one stands aside and views both the contacting has precisely the same motion as the moving line. But if on the moving line, then he sees the lowest point of the wheel absolutely at rest for its instant of contact.

But suppose that one takes his position at the center of the wheel. The highest point of the wheel will appear to be moving forward in the direction *C* while the lowest point will seem to be moving in the opposite direction. In fact, *with reference to the center* the particles of the wheel will have a movement of rotation.

There are thus two rotations going on all the time. The entire rolling body rotates *for the instant of contact* about the point of contact. This center of rotation is constantly changing, however. The central particle of the rolling body, on the other hand, always remains a center of rotation.

Further, if there is a second contacting surface, as in Fig. 2—this second surface effecting the driving of the circle—then *relatively to this moving surface* there is for the moment of contact a center of rotation. This instantaneous center of rotation—the upper point of contact—moves backward relatively to the driving surface.

Much the same may be said in reference to straight and tapered rollers in a roller bearing. There is a central line consisting always of the same particles and relatively to which all the remaining particles rotate as about an axis. It is the *axis of rotation*. Then, diametrically opposite each other, are two lines of contact. Each of these is an instantaneous axis of rotation quiescent for the moment of contact but immediately succeeded by another. Thus in Fig. 3, the line *DE* is the axis of rotation. In the body of the roller, the particles of material along this axis are such that if they be regarded as quiescent, every other particle will be seen to rotate about their line of distribution. The lines of contact of the roller with the race ways are the two instantaneous axes of rotation.

The motion of each of the particles of the wheel Fig. 1, is the compound of two distinct movements—(1) motion in a direct line given by the arrow *C* and (2) motion of the point as it rotates about the center of the wheel. Both uniform, we see that at *B* both motions are in the same direction, while at *A* the directions are the opposite. Further, as learned, there is no motion of a particle at the moment of rolling contact. So then at *A* the velocities of the contrary motions must be the same in order to produce this quiescence. We have now arrived at a most important principle—the forward velocity of a rolling body is just equal to its peripheral velocity. And, further since at *B* both are in the same direction, we have the principle that the velocity of the point of the periphery furthest removed from the point of contact is just double the forward velocity. So that (Fig. 2) the velocity of the driving surface *K* is double the forward velocity of the driven circle. These are most important propositions, and are true whether the plane of rolling is perpendicular or inclined to the surface upon which the rolling is done.

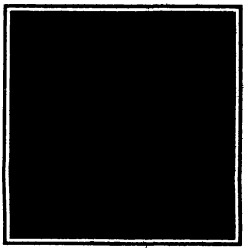
Without going into the mathematical proof it may be stated that in consequence of principles already enunciated the axis of rotation and the two instantaneous axes of rotation are three lines meeting in a point. Further, if the rolling bodies are balls or rollers revolving about a shaft, then the axis of this shaft must pass through this point of intersection. Thus in Fig. 3, these four lines all meeting in one point are *DH*, *DE*, *DF*, *DJ*.

In ball and roller bearing design, this requirement becomes of first rate importance. Thus the four-point ball bearing shown in longitudinal section in Fig. 4 is correct in design in so far as the convergence of these four lines are concerned. But some may have difficulty in seeing that a rolling ball has an instantaneous axis of rotation as well as a roller. Reflect, then, that both the points 1 and 2 of the ball in Fig. 4 are absolutely at rest for the infinitesimal moment of contact. They determine, therefore, a line of quiescence equally with a roller. Similarly, the points 3 and 4 are at rest relatively to the driving ball race—and determine a second instantaneous axis of rotation.

In Fig. 5 the instantaneous axis of rotation determined by 5, 6 intersects the axis of the shaft at *O*. This gives *OC* for the axis of rotation. Similarly 7, 8 yield the line *QO* as the axis of rotation. We have, therefore, two conflicting axes of rotation. The design of the bearing is consequently incorrect.

The friction arising from compression is an important matter. In Fig. 6 *GK* is one of the instantaneous axes of rotation. The ball is flattened by compression at the points of contact, the one region of contact being represented by *FD*. At the instant of contact the ball is rotating on *GK* as an axis. This means that every point along *FD* is rotating in a plane perpendicular to *GK*. The result is that all along *FD* there is a sliding taking place relatively to the race way. The point *D* is moving in a circle whose center is *C* and radius *DC*. There is, then, sliding friction, effective over the whole area of compression. The pressure corresponding to the slide is in the direction *GK*. The seriousness of the friction, then, is dependent upon the pressure in this direction. The size of the compression is due to the pressure perpendicular to *FD*. By suitably designing the race ways, the pressure in the direction *GK* may be made small, although it may be unavoidable to keep large that in the direction perpendicular to *FD*. The way to do this is to diminish the angle *DBC*. A design such as that shown in this figure (6) is to be condemned on account of the large size of this angle between the race way and the instantaneous axis of rotation. In Fig. 7 a correct design is shown. If we observe in Fig. 6 that *AHB* is an isosceles triangle, we readily see that angle *DBC* is one-half the supplement of the angle of the groove *AHB*. Consequently, if we desire to make *DBC* small, we see to it that *AHB* is large. Thus, by making *AHB* = 170 deg., the angles between the instantaneous axis of rotation and the faces of this race way are reduced to 5 deg. each. For such angles the pressure in the direction of *GK* is well-nigh negligible. This means that the sliding friction due to compression is practically eliminated.

A further question that arises in designing ball and roller bearings relates to the use of separators. In Fig. 8, it will be readily seen that at the point of contact between two balls (or rollers) there is a slide, the surfaces in fact moving in opposite directions. The question arises: Should balls be prevented from mutual contact so as to eliminate this source of sliding friction? To answer this it is necessary to know whether the slide occurs under pressure. For despite the slide, the friction would be negligible if there is little or no pressure from ball to ball. The writer has made a very complete mathematical inquiry and found that balls and rollers probably do press upon each other with a considerable percentage of the load, so that separators are to be regarded as advisable. If used, however, they should be rolling separators. The introduction of a non-rolling separator will not result in eliminating sliding friction. But by properly using a rolling body—a ball or roller—this friction may be avoided. Fig. 9 shows that the small separator ball is competent to partake of the contrary motions of the bearing balls.



A CURIOUS STAR MAP

The position of the separator should be noticed, as no other position seems allowable. The center of the separating ball should be in the straight line joining the centers of the bearing balls which it separates. For if it be located above or below, the pressure of the bearing balls will force it out or in. In either case, a new source of friction will arise from the rotation under pressure of this ball against parts of the bearing.

To hold the separator in place, some suitable means is required. The separating ball will of course rotate against the holder. But what is important is the fact that this rotation occurs without pressure. This is secured by the position of its center on the line of centers of the bearing balls.

There are a number of methods of retaining separator balls in position. Thus, in the double ball bearing, Fig. 10, there is a small tube in which the separator lies. This tube is funnel-shaped at each end. These funnels serve to compel the centering of the tube with the bearing balls. That is, when the bearing balls press against the two funnels, the axis of the tube is made to coincide with their line of centers, and this brings the center of the loosely held separator ball into its proper position.

In Fig. 10 is shown a radial bearing of the Chapman type. The tube with a funnel at each end may be clearly seen. Within the tube lies the separator ball, whose office it is to harmonize the contrary motions of the adjacent bearing balls. Of course, the ad[illegible] ment that the [illegible] bearing balls [illegible] to crowd [illegible] upon the separator [illegible], the contact with [illegible] is either slight or nothing at all. It is [illegible] however, that the funnel and the bearing ball [illegible] touch or approach each other fairly closely, as otherwise the centering of the tube with the line of centers of the bearing balls could not be counted upon to take place.

Ostrich Farming in Australia.

The first attempt to raise ostriches in Australia was made by a Mr. Malcom, who in 1880 brought 100 young birds from South Africa to South Australia. In the following year the parliament of South Australia enacted a law which granted to the first person who should exhibit 250 ostriches, more than one year old, about 2 400 acres of land suitable for ostrich farming. The conditions were satisfied by the South Australian Ostrich Company, which was founded in 1886, with a capital of $75 000. The company received land near Port Augusta on Spencer Bay, but in spite of this assistance the company has never paid a dividend, although it now possesses 1,190 ostriches, all of which were imported from South Africa. There is a still larger ostrich farm on the shore of Lake Albert, and smaller farms are scattered through the colony.

In New South Wales, ostrich farming was first attempted in 1897, by Barracluff, who imported six pairs of ostriches from northern Africa, and now possesses 64 birds.

Queensland and Victoria possess only small ostrich farms, which have not produced very encouraging results. In all, there are now about 2,000 ostriches in Australia. The inferior feathers are used at home, and the more valuable ones are exported chiefly to Germany.

A CURIOUS STAR MAP

It would be more respectful to call this invention an "astronomical umbrella," but so many terms of humorous turn have been applied to the umbrella since the days of Jonas Hanway that it would be difficult for anybody except a boy scout to take this invention quite seriously.

The inventor, Mr. McEwan, is a Scotchman, and he has designed this apparatus for the study of the stars. The constellations and the Milky Way are all in their places, "ship-shape and Bristol fashion."

Just why an umbrella should have been used for this astronomical purpose surpasses our comprehension. In broad daylight such a chart would be obviously useless, and at night time nearly useless because of the difficulty of seeing the map at all.

Utility of Beekeeping.

Beekeeping is a valuable aid in the cultivation of fruit and seed crops. Insects which feed on nectar play an important part in the fertilization of flowers. Fertilization is effected in other ways, but the agency of insects is the more certain and efficacious, and no other insect is comparable with the honey bee in this respect. A strong hive contains 10,000 bees in February, 15,000 in March, 40,000 in April, and from 60,000 to 80 000 in May. It has been discovered by skillful observers that the average load of nectar carried to the hive by a bee is about 3/10 of a grain, so that the collection of one pound of nectar requires nearly 23,000 foraging excursions. By means of hives set on balances it has been found that the daily increase of weight in May averages 3.3 pounds. Occasionally, more than 11 pounds is gained in one day, and when the amount consumed by the bees and the loss of weight by evaporation are considered, it appears probable that the average daily quantity of nectar collected is not less than 11 pounds, which would load 256,000 bees. As a bee visits 10 flowers on the average in collecting a single load, some 2,560,000 flowers are visited in one day by the bees of a single hive. An additional large number of visits is required for the collection of pollen. These figures explain why many trees and plants bear small crops in the absence of bees.

The bee is charged with various imaginary crimes. Its sting is formidable, but chiefly to the imprudent. It is accused of ravaging fruit, but its tongue is formed exclusively for the extraction of sweet juices, and its mandibles are unable to pierce the skin of a fruit. Grapes have been taken intact from the interior of a hive in which they had been allowed to remain [illegible] days. A grape which had been smeared with honey was licked clean, but was not injured. The bees inserted their tongues in pinholes made in the skin of a grape, and extracted some of the juice, but they were unable to enlarge the holes. In some [illegible] bees are menaced by insecticides intended for other insects. At [illegible], Italy, in 1907 all the bees [illegible] killed by spraying the olive trees with [illegible]

Correspondence.

THE SELDEN DECISION.

To the Editor of the SCIENTIFIC AMERICAN:

Your editorial in the SCIENTIFIC AMERICAN of September 25th on "The Selden Patent Case" interested me, as it seemed to me that the claim could be met without much trouble. Upon a cursory examination of my class of fire extinguishers, portable, wheeled, I find a patent to Bean, No. 75,348, March 10th, 1868, which shows every essential element of the claim in question, the single distinction in terms coming from the use of a steam engine instead of a gas engine. It would surely seem that this patent could not have been before the court as the decision would have been otherwise.

A. S DENNISON

U S Patent Office, Washington, D. C.

THE NUMBER OF OUR ANCESTORS.

To the Editor of the SCIENTIFIC AMERICAN

In the discussion of the "Number of Our Ancestors" in these columns your correspondents have been misled by the use of the word "ancestor" where kinship is defined. Under the great theory of the origin of life in a single cell or protoplasm, all living creatures are kin, and the number to which each individual is related is the total number which have been born into the world at the moment of the computation. The number for the preceding moment was something less, and if we go back the length of time embraced in a generation of mankind, the number in the kinship of the human family is many thousands less The further back we go toward the genesis of things the smaller the human family, and the number of one's ancestors certainly could not have been in an inverse ratio, as some of your correspondents have stated

The term "ancestor," however, cannot and does not mean the same as "kinship", nor, in its true sense, does it apply to more than the father and mother in each family The line of descent is a single thread running back through all ages to the very beginning of life, and in the social system of the present day the line is accorded to the male, but it could be as true of the female, it cannot be accorded to both, however, else the tangle which would ensue would strain and break the thread. These threads of anthropological progression are best conceived as the branches of a tree, living beings of the present being somewhat as the innumerable leaves, and the main trunk somewhere in the dim beginning, but in its formation each thread is like a flowing river where, tracing backward, we find branch uniting with branch, and each branch made up of uniting branch and branch, smaller and smaller, until even the rain drop is reached

So, with the infinite insight of the Creator we might start with any human being that ever lived, in any age, in any place, of any race or color, and by that single thread trace it back, back, back to the beginning previous to the first branching. And as we so trace each life thread we may count at each branch an ancestor for the direct descent and add one, the branch of the opposite sex there uniting—two in each generation—and no more, all else are but kin. Therefore the number of our ancestors resolves itself into the simple problem of the number of branches (generations) through which the individual has come multiplied by two.

CHARLES FRANCIS ADAMS.

Hampton, N H

Protection of Sown Crops from Crows.

Graminivorous birds exhibit, as experiments have proved, a marked aversion to foods of peculiar form and color, and also to certain aromatic and bitter substances. It has been found possible to give to seeds, without affecting their germinating qualities, flavors, odors, and colors which protect them from the attacks of crows, by the employment of cheap substances and simple methods of treatment. Suitable colors were found in Prussian blue, signal red, and anilin green. The pigments were strewn over the seed, which had been moistened with gum water. The seeds were then thoroughly mixed by shoveling and acquired a deep color. For the purpose of giving seeds a peculiar taste, pulverized alum and sodium sulphate, tobacco extract, and "Sohtenin," an insecticide used for foliage, were tried, but none of these substances materially altered the flavor of the seeds. Good and lasting results were obtained only with pulverized aloes, which also changes the color of the seeds over which it is strewn. A repulsive and persistent odor was given to the seed, without affecting its ability to germinate, by a weak solution of creolin.

In one series of experiments crows were fed with [illegible] of seed contaminated with [illegible] and the amount of seed left [illegible] in each case [illegible]. In another series, [illegible] were sown in [illegible] [illegible] applied to practice, the investigation proved that crows are influenced by color, taste and smell in their choice of food. Blue proved to be particularly repugnant, but green seeds were eaten very reluctantly, while red exerted a much slighter protective influence The treatment with aloes was especially effective. Although it produced very little change in the appearance of the seed, the rows sown with seeds so treated were destroyed only in spots. The seeds treated with creolin were also avoided, but "Sohtenin" proved wholly ineffective.

In continuing the experiments it will be especially advisable to try the effect of mordant dyeing on a large scale. Blue dyes appear the most promising, but the best results will probably be obtained with appropriate combinations of colors, flavors, and odorous substances.

◆

Relation of Size to Speed in Ships.

BY SIDNEY G KOON, M M E.

Mere size as an asset has considerable value, especially when it comes to a question of naval vessels. That this is so was strikingly illustrated a few years ago in a large shipyard, when it came to a question of the design of a fast cruiser to fulfill certain specified requirements. As a matter of fact, the cruiser was never built, but the calculations were made based on a set of lines which gave good model results, and the comparisons herein instituted are the fruit of considerable careful thought along the lines of the conflicting elements entering into the design of the modern warship

The original design embodies requirements that the vessel should carry a battery of two 8-inch and ten 5-inch guns, with four 3-inch automatic guns and two torpedo tubes, at a maximum speed of 23 knots. The coal carried on "normal" displacement was to be sufficient to carry the ship at 23 knots for a distance of 1,500 nautical miles. The hull was to be sufficiently strong to withstand at this speed the buffeting of a heavy sea.

The model test indicated an attainable admiralty coefficient of 240, based on shaft horse-power The steaming radius was calculated on an assumed consumption of 1 6 pounds of coal per shaft horse-power per hour The (turbine) machinery was designed and found to promise one shaft horse-power on 140 pounds everything included As worked out on this basis, the vessel was to have a length of 420 feet (waterline), a beam of 49 feet and a draft of 19 feet, the displacement, with block coefficient of 0 408, being 4,560 tons.

The horse-power required was computed by the usual admiralty formula

$$H = \frac{D^{2/3} V^3}{K}$$

where H is the horse-power D is the displacement, 4,560 tons ($D^{2/3} = 275$), V is the speed, 23 knots ($V^3 = 12,167$), and K is the admiralty coefficient, 240 H thus becomes 14,000, and the weight of machinery 1,960,000 pounds, or 875 tons. The fuel required at full speed is 22,400 pounds (10 tons) per hour, or 649 tons for a run of 1,500 nautical miles at 23 knots.

Of the other weight, 40 per cent of the displacement was allotted to hull and fittings complete (1,824 tons), 10 per cent to full equipment and stores including the officers and crew and effects (456 tons) another 10 per cent to a protective deck, the maximum thickness of which was 2¾ inches, while the remaining 300 tons took care of the battery, ammunition, and ordnance spares. The battery was practically without protection

While this design was under completion the question of a higher speed was mooted all other requirements as outlined above being fulfilled A design was thus prepared, the main dimensions of which were Length, 454 feet, beam, 53 feet, draft 20 feet 16 inches and displacement, 5,750 tons. The horse-power for 23 knots was found to be 16,300, which calls for 760 tons of coal to cover the stipulated radius of 1 500 miles

The weights of hull and of equipment and stores bear, naturally, the same ratio to the displacement as with the parent ship They are thus 2,300 tons and 575 tons, respectively The protective deck having the same thickness and general distribution as in the first case, weight 532 tons. The battery weights are constant at 300 tons. The sum of these five items gives a weight of 4,467 tons, which leaves 1,283 tons for machinery On the basis of 140 pounds per horse-power, this allows for 20 500 horse-power

Using the admiralty formula once more,

$$V^3 = \frac{HK}{D^{2/3}},$$

where H is 20,500, K is again 240 and $D^{2/3}$ is now 321 V^3 becomes 15,327, V is 24 84, or a speed of 24 84 knots may be expected to be realized It is thus seen that an increase in displacement of some 25 per cent here permits an increase of nearly 2 knots in speed

With the idea of determining to what extent further alterations in dimensions (while still preserving the original lines, proportions and general set of requirements) would affect the result, four other cases were briefly studied, two of vessels smaller than the first, and one much larger than the second The general characteristics of these four (C, D, E, and F), as well as of A and B, are shown in the accompanying table, the calculations having been made in each case as outlined above It will be seen that an increase in size to 8,900 tons (not quite double the original) brings the speed up to 27 9 knots, with 38 800 horse-power

Weights.	A	B	C	D	E	F
Hull and fittings	1 824	2 300	1 152	1 496	2,728	3,560
Equipment and stores	456	575	288	374	682	890
Protective deck	456	532	335	400	597	711
Battery and ammunition	300	300	300	300	300	300
Machinery and water	875	1 283	227	602	1,063	2 426
Fuel	649	760	478	568	850	1,013
Total displacement	4 560	5 750	2,880	3 740	6,820	8,900
Total horse power	14,000	20 500	3 630	9 650	26,000	38,800
Horse-power for 23 knots	14 000	16 300	10 250	12 200	18 250	21 750
$D^{2/3}$	275	321	202	241	360	429
V^3	12 167	15 327	4,318	9 610	17 731	21 706
V, or speed in knots	23 00	24 84	16 28	21 26	26 08	27 9
Length of water line feet	420	454	360	390	480	504
Beam, feet	49	53	42	46½	56	61½
Draft of water, feet	19	20¼	16¾	17⅝	21⅝	23⅝

It will be noted that, after satisfying all other requirements, the design marked *C* has left only 227 tons to devote to machinery thus allowing for but 3,630 horse-power This would make possible a speed of only 16 28 knots Hence, the provision of covering 1,500 nautical miles at a speed of 23 knots is a manifest impossibility To reach this speed, 10 250 horse-power is required calling for 641 tons of machinery If this speed is required of this ship and all other demands be met except steaming radius we find that we have left only 64 tons for coal which would correspond with a radius of but 201 nautical miles. Similarly with *D*, 23 knots calls for 12 200 horse-power and 763 tons of machinery This reduces the coal supply to 407 tons, and the steaming radius at 23 knots to 1,075 miles.

This study of course neglects all variations in results which might accrue from variations in the conditions imposed Thus, by reducing factors of safety, lower hull weights could be obtained and this is frequently done especially on the smaller ships In the same way more power might be obtained from a given weight allotted to machinery In this manner the smaller vessel might be made to accomplish the results here attained only by the larger But such methods are obviously inadmissible where strictly comparative results are desired and especially so where the effect of a mere change of size is to be determined

The Current Supplement.

In a paper entitled The Origin of Life,' read by Prof E H Starling before the British Association for the Advancement of Science, and published in the current SUPPLEMENT, No 1766 the broad ground is taken that a living organism may be regarded as a highly unstable chemical system which tends to increase itself continuously under the average conditions to which it is subject, but undergoes disintegration as a result of any variations from this average The practical applications of the microscope are pointed out by J E Barnard Some new safety devices for steam boilers are described Of aeronautic interest is an article on experiments with models of airships and aeroplanes in the laboratory and a continuation of last week's discussion of the Paris aviation meeting The Loetschberg tunnel through the Bernese Alps is described by Dr Alfred Gradenwitz E E Carey contributes an excellent article on the electro-chemical age, in which he points out that the science of metallurgy is now entering a new era. The opening of the mounds of the great capital of Egypt is the largest enterprise yet started in that country It will probably take twenty years to complete The preliminary work of 1907-8 at Athribis is described in an article by Prof W Flinders-Petrie entitled Memphis and Its Foreigners." Recent progress in chemistry is reviewed by Prof H E Armstrong

A committee of investigation has been appointed by the American Railway Association to report upon the railways which have adopted electrification This committee is composed of officers of roads which have electrified portions of their lines or contemplate doing so The railways represented on the committee are the Illinois Central Union Pacific Southern Pacific Erie, Delaware and Hudson, and New York New Haven & Hartford A proposal is now before the New York Central lines to lay out considerably over $20 000,000 during the current year, largely for the continuation of the electrification work at the New York terminal Another section of the West Shore road between Syracuse and Utica will be electrified and some double tracking elimination of level crossings and gradient revision will be carried out around Rochester and Buffalo A considerable amount of new equipment will be purchased.

THE 10,000-TON SUCTION DREDGER "LEVIATHAN" FOR USE ON THE MERSEY

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

Owing to the increasing draft and tonnage of steamers frequenting the port of Liverpool, the maintenance of an open channel in the estuary is one of vital urgency Dredging upon a vast scale has to be maintained continuously to remove the sand, which threatens to silt up the navigable channel, and in order to carry out this work most efficiently the Mersey Docks and Harbor Board found it necessary to undertake the construction of a special type of dredger The task of evolving such a craft was intrusted to their engineer-in-chief Mr Anthony G Lyster M I C E who is familiar with the peculiar conditions prevailing at this port and who designed the sand pump dredger "Coronation which built in 1903 was at that time the largest and most powerful dredger of its type afloat This latter vessel 332 feet long by 53 feet beam and 20 4 feet deep, with a gross tonnage of 3 943 tons and capable of dredging to a depth of 65 feet with a pump capacity of 4 500 tons per hour proved eminently successful and he decided to design a new craft upon the same broad lines

The new vessel, the 'Leviathan' has now been placed in service and ranks as the largest and most powerful dredger that has yet been placed in operation in any part of the world It has an over all length of 487 feet a beam of 69 feet and a depth of 30 feet 7 inches these large dimensions being necessary to afford the requisite capacity and strength to carry the designed enormous load of 10 000 tons of sand It is of the twin screw self propelling sand pump hopper-dredger type, provided with twelve hoppers having a net total capacity of 180 000 cubic feet and is fitted with pumps capable of dredging and filling itself with this load of clean Mersey sand in 50 minutes from a maximum depth of 70 feet while the propelling machinery is sufficient to enable her to drive this load of 10 000 tons in her normal steaming trim with coal bunkers and water tanks full at the rate of 10 knots under ordinary working conditions and to discharge this load very rapidly The gross tonnage is about 8 000 tons and the full load is carried on a mean draft of 23 feet The fulfillment of these conditions insures the boat s possessing three times the power and capacity of any of the Harbor Board s existing dredgers including the Coronation which is the next largest craft of this description in operation at Liverpool

The vessel constructed by Messrs Cammel Laird & Co the well known British armament manufacturers and naval shipbuilders at their Birkenhead works is built of steel to class 100 A 1 at Lloyds. It has a complete steel upper deck sheathed with wood and is divided transversely by thirteen watertight bulkheads extending from keel to deck There is a longitudinal center line bulkhead dividing the hoppers pump rooms, and boiler rooms as well as No 2 buoyancy spaces on either side of the vessel These subdivisions taken in conjunction with the watertight hopper side bulkheads divide the vessel into about thirty separate watertight compartments The steel structure has been arranged to give special strength to the vessel in view of the great strains developed in loading and unloading the hoppers

The dredging plant of the Gwynne type, comprises four sets of inverted vertical triple-expansion, surface condensing, direct-acting engines having a total indicated horse-power of 2,800, coupled direct to four independent sets of centrifugal suction pumps connected to their respective suction tubes, two on each side of the vessel, with hydraulic sluice valves on the inboard side Each tube has an internal diameter of 42 inches is 90 feet long, and is bolted to a heavy cast-steel swivel bend at the upper end and a strong nozzle of special design at the lower extremity These nozzles are provided with a cast-steel grid, so as to exclude material of such a size as would foul the pump The swivel bends work in vertical slide frames riveted to the vessel's side, with trunnions to permit the suction pipes to hinge about its center and thus permit raising or lowering to conform with the state of the tide during dredging

The suction pipes have an inclination of 45 degrees when dredging to their lowest limit of 70 feet below sea level Each tube is lifted and lowered by two strongly built derricks of steel, one at each end of the tube and stopped on seats at the upper deck complete with blocks and flexible steel wire ropes led on to drums of its respective hoisting winch

Fitted over each side frame are deck slides supported by strongly built seats on deck, to enable the suction pipes with swivel bend to be stowed inboard when not dredging Each deck slide has a heavy cast iron frame of the same section as the slide frame and can be moved inboard or outboard by means of worm gear the same being carefully adjusted so that it comes exactly in the same vertical plane as the slide frame when at its extreme outboard position to permit the suction pipe to be lowered to its working position below the water level

Emergency gear is fitted to each suction tube so that in the event of an accident the suction tubes may be lifted by block and tackle led to the deck winches Two of these winches are placed under the forecastle deck and two on the poop deck The four hoisting winches are inclosed in steel houses fitted with glass fronts so that the winchman within has a clear and uninterrupted view of the derrick lifting and lowering gear Each hoisting winch has four drums arranged in pairs two for raising and lowering the suction pipes and the other two for derricking in or outboard These powerful winches are actuated by double-cylinder reversing steam engines.

The four dredging pumps are arranged to deliver the excavated material along pipes passing up through the deck into two landers and at the point where they joint hydraulic sluice valves are fitted The landers are placed side by side with a center division and run the full length of the hoppers The lander valves worked by worm gear are placed over each hopper on the bottom of the landers, so that the discharge to any hopper can be controlled as desired By these means the valves with control gear are also arranged in the steel division separating the two landers The discharge of sand and water from any or all, of the pumps can be controlled so as to trim the vessel as necessary

The hoppers placed forward of the pumping-engine room are built in twelve separate compartments, six on each side of the center line bulkhead Each is fitted with Lyster's patent valves having an opening 5 feet 6 inches in diameter through the bottom of the vessel The hopper bottom plating has a steel slope in the four directions down to the edges of the valve seat bottom casting for quick discharge of the sand.

THE 10,000 TON DREDGER "LEVIATHAN,' WITH A 500-TON SAND PUMP DREDGER ALONGSIDE.

SOME CURIOSITIES OF INVENTION.

From time to time we have collected in these columns instances of perverse mechanical ingenuity as well as misdirected efforts on the part of inventors, partly for the purpose of amusing the more soberminded, and partly as an instructive object lesson. On the opposite page will be found a number of such mechanical curiosities, some of them without any excuse whatever for their existence, others not without merit. We are indebted to the Illustrated London News for these examples.

The man who invented the padded chair and traveling carrier to prevent serious street-car accidents was evidently as much concerned with the comfort of the person to be saved after collision, as with the mere act of saving He has provided a fender which consists of a traveling belt and which serves the kindly purpose of conveying its human freight to a comfortable chair It would seem from the illustration that the man to be saved is expected to be picked up in a sitting position facing forward so that he may be conveniently lodged in the padded seat. If he were picked up prostrate, he is presumably either dead or unable to sit, for not otherwise can we account for the chair

The umbrella cap which emanates from the mind of another inventor certainly ought to serve its purpose of shielding the wearer from rain and sun if one may judge from the illustration It is assuredly no uglier than the headgear in which civilized man now disports himself

The method illustrated for arresting a runaway horse is certainly one of the wildest fancies which we have ever seen The plan is nothing more or less than simply to lift the runaway horse bodily by using a derrick Presumably the driver is to manipulate the derrick boom Surely only a Titan could succeed in raising even the half-starved animal that is harnessed to the average tradesman s wagon.

The inventor of the horse velocipede pictured was concerned chiefly with the preservation of roads and horses' shoes He places his horse upon a kind of treadmill which is operatively connected by crank mechanism with the road wheels. Presumably this wheeled horse is to be used as a kind of locomotive to draw the car

The many disasters at sea have no doubt, inspired the inventor of the combined waterproof coat and life raft which is illustrated A central hollow structure is connected with a waterproof coat into which the passenger crawls and thus makes himself literally part of the life raft Inasmuch as a hollow mast is provided to supply air to the interior of the life raft and water and inasmuch as provisions are there stored, the man in the rubber coat must have access to the interior A counter weight is provided to enable him to keep the raft in proper trim

The inventor of the cigar holder for hats which is also to be numbered among these curiosities, seems to have been dismayed by the waste space in an ordinary "bowler" hat, for he has devised a means of utilizing the unoccupied space in a way which leaves one to infer that he never heard of pocket cigar cases.

We believe that something like the sporting dress here shown has actually been used, but certainly not equipped with the hand-operated screw propellers. As shown in the detailed view, separate air-tight chambers *a a* are employed, which are protected

SOME CURIOSITIES OF INVENTION

THE ATTITUDE OF DIPLODOCUS.

Readers of the SCIENTIFIC AMERICAN are familiar with the prehistoric animal known as "Diplodocus," the largest of dinosaurs. To the American Museum of Natural History, and particularly to Prof Henry Fairfield Osborn, president of the Museum, is due much credit not only for the arduous work of excavating the bones of this and other extinct creatures in the far West but also for painstaking care in correctly mounting the skeletons.

The donation of a Diplodocus skeleton through the kindness of Mr Carnegie to the Berliner Museum fuer Naturkunde has brought this extinct animal much into the public eye in Europe Dr Tornier is largely responsible for this increased popular interest in palæontology because of the paper which he recently read before the Gesellschaft naturforschender Freunde on the structure of the Diplodocus skeleton in the Berliner Museum a paper based largely upon the studies of Hay and therefore hardly the result of original investigation The Berlin diplodocus is mounted in the attitude of a mammal, with extended legs Tornier holds that its posture should have been more reptilian We abstract from Umschau an account of Tornier's views Dr Tornier argues that four-footed lizard like reptiles rise but little from the ground even when in active motion that the humerus and the femur move in approximately horizontal planes, so that the animal crawls rather than walks. The Diplodocus was a reptile a giant lizard in other words. Tornier holds that the skeleton has been incorrectly mounted and that its posture should have been that indicated in Fig 1 rather than that indicated in Fig 2 If the animal had been mounted as in Fig 1, it would have walked somewhat like a crocodile, which, in Dr Tornier's opinion it did

In the reconstruction of Diplodocus the hind feet rest flatly upon the ground, whereas the fore feet touch the ground with the toes only Hatcher who was one of the first to study the animal closely thought that perhaps the fore feet were placed flatly upon the ground Holland disputed this view Dr Tornier believes that Holland was right, because reptiles do not tip-toe with their fore feet and because, so far as we know, there is no land animal which employs only the toes of its front feet and the soles of its hind feet in locomotion

Dr Tornier holds that the tail of Diplodocus was a far more important member than the mounters of the skeleton suspected In the Berlin model only the end of the tail rests upon the ground the remaining portion rising at a fairly sharp angle to join the lumbar vertebræ He stated that in order to mount the tail in this manner and to produce the pronounced curve of the reconstruction it was necessary to spread the vertebræ of the tail He states that the caudal vertebræ of lizards are never separated in this fashion, but that they are more or less locked together Inasmuch as the Diplodocus vertebræ are reptilian in form he believes that here again an error was made and that the tail did not curve up sharply from the ground but that it projected rearwardly in a slightly curved line as in all reptiles In the restoration only one-half of the tail rests upon the ground, the other half rising free into the air If this were correct the rear extremities of the animal would have been compelled to support an enormous load of bone which served no useful purpose. In typical four-footed lizards it is the function of the tail to guide the animal. As soon as the animal begins to move, the tail stiffens the spinal column, thereby enabling the animal to proceed rapidly along in a straight line. If the tails of such animals be cut away, they seem to be no longer able to move properly It was the purpose of the tail of the Diplodocus to stiffen the lumbar vertebræ, as in the case of all lizards, when the animal was in motion. Moreover, it served to counterbalance the head of the creature and to prevent it from tipping over forward, particularly when it was traveling down an incline.

Dr Tornier is of the opinion that Diplodocus did not hold its head horizontally but that the neck was habitually curved in the form of an S Holland also made this assumption and likened the head and neck of Diplodocus to the head and neck of an ostrich The evidence for this attitude of the head is to be found in the peculiar ball-and-socket connection of the neck vertebræ It was the object of this form of articulation to enable the neck to be extended to all sides as well as up and down

Fig 1.—Tornier's conception of the true position of Diplodocus.

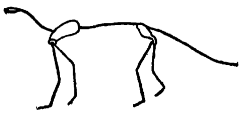

Fig 2.—Present mounting of Diplodocus.

It must not be assumed that Dr Tornier's criticism of the mounting of Diplodocus meets with general European approval Dr Fritz Drevermann, curator of Senckenbergisches Museum Frankfort-on-the-Main, believes that there is room for two opinions. He points out that Dr Tornier's conception of the position of the legs of Diplodocus is based on Hay's view If American students and particularly Prof Osborn (under whose direction the Frankfort Diplodocus was mounted) Hatcher Holland, and the Viennese Abel regard the present position as correct, it is not likely that Tornier is right. It is inconceivable that the palæontologists of the American Museum of Natural History who have mounted Dinosaurs by the dozen, are ignorant of reptilian skeletons

Marcellin Boule professor of palæontology at the Museum d Histoire Naturelle, Paris, agrees with Drevermann He too argues that American authorities are fairly in accord on Dinosaur reconstruction and that the few disagreements affect only minor details. Inasmuch as Americans alone have had an opportunity of finding Dinosaurs in any number, and therefore have had the best opportunity of studying them, their opinion must be accepted as authoritative. He quotes B. P Hay, who does not agree with most American students and who seems to have inspired [illegible] Prof. Boule contends that Tornier is wrong in [illegible] that mammals have one form of locomotion and reptiles another The conclusion that because Diplodocus is a reptile it must crawl is not necessarily valid. Locomotion is dependent upon external conditions. As a matter of fact there was once a time in the history of the earth when reptiles were lords of widely different elements. They dominated the water as Ichthyosaurs, Plesiosaurs and Mosasaurs, they roamed the earth as Dinosaurs and navigated the air as Pterosaurs. If present reptiles are limited to a crawling movement that is by no means conclusive proof that they always crawled.

◆

Chartreuse Liqueur Decision.

Consul C P H Nason, of Grenoble, submits the following report on the French legal decision concerning the name "Chartreuse" as applied to liqueurs

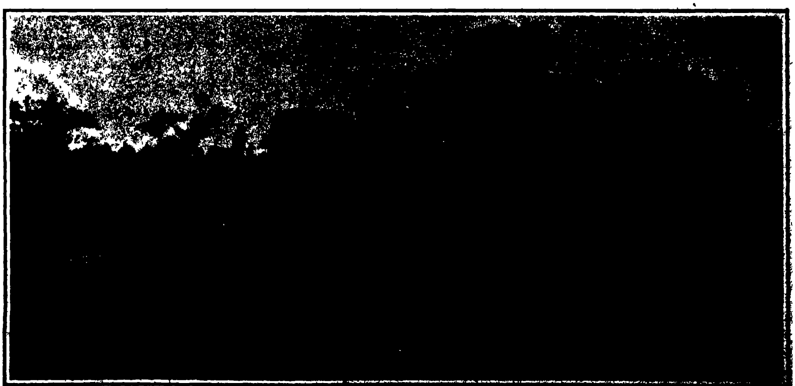
The court of appeals at Grenoble on June 22nd rendered a decision in the long-discussed case turning upon the rights involved in the public sale and use in France of the trade-mark "Chartreuse." After the expulsion in 1903 of the Carthusian monks from their convent, La Grande Chartreuse, the making of the well-known liqueur (the distilling of which and the aromatic plants entering into its composition were claimed to be known) was intrusted on the part of the state receiver to a prominent French distiller The latter, as against the sale by auction of the very valuable trade-mark under which the liqueur was universally known, made a written advance offer, on the basis of which the bids were to begin at 1 500,000 francs ($289,500) Thereafter came forward a second party and guaranteed the receiver an auction offer of 5 000,000 francs ($965,000), but this was finally reduced to 3,000,000 francs ($579,000)

This agreement the second party failed to keep, he withdrew the offer, and as a consequence, at a forced sale to the highest bidder the right to the trade-mark was sold to a company formed by the first party for the sacrifice sum of 502,000 francs ($96,886) Whereupon the receiver brought suit against the second party for breach of contract, and the latter, after a strongly contested trial was condemned by the civil court of Grenoble to pay the former for non-execution of contract 1,094 000 francs ($211,142) An appeal was taken from this judgment, and after another prolonged hearing and arguments by eminent advocates, the court has not only affirmed the fault and responsibility of the second party, but increased the damage interests to be paid the receiver to 2,438,000 francs ($470,534)

The use in this country of the trade-mark Chartreuse was decided by the two lower United States courts against the Chartreux monks and in favor of the new French company An appeal is, however, pending

◆

According to the latest statistics, the total peat bogs of Sweden would be capable of producing 10,000 millions of tons of air-dried peat, suitable for fuel. This quantity, as compared with the present import of coal, would be sufficient for a period of 1,500 years. More exact examinations of the geological character of the peat bogs will soon be started by the Swedish Geological Society



THE HAGENBECK RESTORATION OF DIPLODOCUS, IN WHICH THE AMERICAN MUSEUM OF NATURAL [illegible]

[illegible]

By [illegible]

It is a far cry from the day when Aristotle propounded the doctrine that birds hibernate like wood chucks, to the present time, yet much of the mystery which that early naturalist sought to dispel still lingers about the wonderful phenomena of migratory movement.

Only in birds (unless we except fishes) is true migration instinct found. Erratic, semi migratory movements of insects take place; scarcity of food or some other strongly compelling cause induces, from time to time, a semblance of migration among some of the mammals, but only the winged and feathered inhabitants of the globe exhibit a seasonal rhythmic swing from south to north and *vice versa*.

Our modern knowledge embraces much data respecting the actual migratory movement, its date of commencement, duration, and termination, the termini of the journey, the route followed, and the manner in which the traveling is performed. We have accumulated a great mass of statistics concerning the time in spring and fall when certain feathered wanderers may be reasonably expected to appear at a given point along their route. We know that the method of performing these journeys varies much between species, as in length of flight that takes them from winter to summer homes and return, whether they fly almost continuously or by short, leisurely stages, whether flights are mostly by day or night or both, the route followed, and whether this is changed by varying weather or other conditions. We also know that certain species perform their flight to their northern summer homes along one route, and return to their southern winter homes by a widely different course It is well established that some species flock and fly almost entirely by themselves, that others are found widely scattered among flocks of other species, that in still other cases two or three species may almost certainly be found flocked together, while in some instances the flight is performed more in an individual and straggling manner It is a fact well known to many gunners that the course and manner of certain species of migrating birds has been changed materially within recent years, perhaps permanently, and that temporary changes of this character constantly occur, due to easily recognized causes. That class of birds whose life cycle is, perhaps, best known is naturally the one which includes those classed as game birds Notably, as regards migration, these birds fall readily into three divisions: the water fowl, including ducks, geese, and swans, the Limicolæ or shore birds, principally the sandpipers and plovers; the gallinaceous birds such as the bob-white or quail and the ruffed grouse or partridge.

The southward fall migration of the first-mentioned division may, perhaps, be readily ascribed to search for wide and rich feeding areas, where open water is assured; the northern flight to a similar picking of ample breeding grounds. While the southward flight is in some few instances continued as far as the West Indies and South America, in the main the movement is only sufficient and in general seems to conform to the same standard. In suitable localities on the New England coast and about Long Island we find the permanent representatives of their [illegible] [illegible] the flight of [illegible] winter, while in the wonderful breeding grounds along the coast of North Carolina, their numbers seem only to be limited by the persecution of the gunners. The northward journey of the members of this division it is true, is for the most part extended well into the Arctic or sub-Arctic regions, but this is largely a matter of necessity, to secure sufficient areas of suitable nature where they may breed in peace Where birds of this division are not harrassed in late winter and spring by shooting it has been found that they often remain in considerable numbers to breed, much further south than the usually ascribed southern limit of summer residence

On the other hand the migratory movement of the second division mentioned is one of the most extreme known Such birds as the golden plover, black bellied plover, buff breasted sandpiper, and others of their kind are startling examples of the most wonderful migration flights. The golden plover breeding within the Arctic Circle often extends its quarters as far south as Patagonia. Of necessity the breeding season is short, but nearly six months is spent in winter homes. About four months of the year is spent in their spring and fall journeys, which are sometimes as much as 3 000 miles in length In spring they travel northward *via* the Mississippi Valley but in fall they go south by the way of Labrador and Nova Scotia from the latter point launching out to sea and in favorable weather often making a trip of 2 400 miles to South America without a known stop There seems good reason to believe that this avoiding of our coast has increased in frequency since the shooting of the birds by the barrelful so reduced their numbers and endangered a coastwise journey overmuch

The black bellied plover breeds equally far north and on this hemisphere winters in the West Indies Brazil and Colombia The buff breasted sandpiper summers as far north as the Arctic coast and winters south of Uruguay and Peru Migratory movement in all such birds has been undoubtedly affected by changed coastal conditions and excessive shooting

The third division represents birds that are practically unaffected by migratory instinct The bob-white and ruffed grouse are permanent residents where found, till adverse circumstances force them to leave or extermination removes them from a locality

The most fundamental factor in migration the cause remains practically unknown so far as birds in general are concerned The formerly attributed cause and the one which still figures largely in the popular mind, and seeking of a comparatively equitable climate by birds in their journeyings north and south, has long been abandoned by the ornithologist The question of food supply only offers partial solution This is true of other tentative causes advanced It seems probable that a number of causes in a great variety of combination contribute

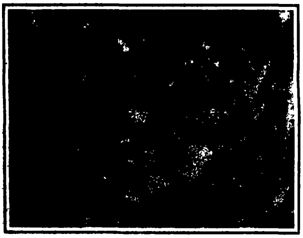
In the study of migration one fact seems to be unmistakably established namely the existence of an instinct that enables birds in flocks or individually to perform migratory flights of great length and to return with great precision to the breeding spot of the previous year Thus we find birds that breed gregariously as gulls terns herons and others yearly returning to the same island strip of beach marsh or swamp in a colony and about the same time each year In the same way our common birds that are more or less solitary in their nesting habits return in many instances to the same spot year after year The bridge girder the beam in the cow shed or the molding on the porch pillar that has this year held a phœbe's nest will ten to one hold such a nest next year It is not exceptional to note on the limb of a village shade tree the occupied nest of the Baltimore oriole the weathered last year's nest and the battered remains of the nest of two years ago A last year's nest of the vireo is often a good clue to the immediate whereabouts of an occupied nest Robins nests are not infrequently built on the remains of the domicile of the year before A hawk's nest is often used for many years in succession and this is particularly the case with the fish hawk or osprey whose nests thus added to year by year often become very bulky with the underpart or foundation a crumbling mass of age-decayed matter Woodpeckers who seldom use the same nest twice often have two or more excavations in the same stub the nesting cavities of successive years

All this evidence of a return of individual birds to a given locality is of course not absolutely conclusive It is seldom possible to adduce such conclusive evidence The reasonable conclusion however must be that the weight of evidence is in favor of the theory

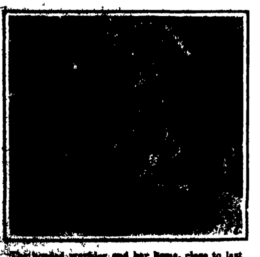
(*Continued on page 3[illegible]*)

The osprey's nest to which the birds return year after year

The downy woodpecker at home, a non-migratory bird



The nest of the Florida gallinule built for years in the same site, even after the marsh has become the center of a hustling city section



The hooded warbler and her home, close to last year's abode.

When the royal terns make their annual return to their island home

BIRD MIGRATION.

THE OPHTHALMO-DIAPHANOSCOPE.

The ophthalmo-diaphanoscope is an instrument for examining the fundus, or back of the human eye. It is the invention of Dr Carl Hertzell, of Berlin who claims that the instrument and its accessories supersede anything that has previously been in use. Briefly, the instrument consists of an eighty candle-power electric lamp which the patient holds in his mouth, as far back as possible This highly illuminates the retina of the eye from the back, and the surgeon looking at it from the front, is able to make a much more satisfactory examination than was possible by means of reflected light and eye-mirrors

Of course the examination takes place in a totally dark room while the patient wears a black mask over his face in order to concentrate the effect of the illumination holes being cut in front of the eyes, through which the surgeon makes his observations

These are the essential points connected with the ophthalmo-diaphanoscope and its working There are, however a few other details connected with the invention which are of particular interest. The illumination which is concentrated at one end of the tube is ten times more powerful than that which is emitted by any other lamp previously employed in surgery for transmitted light As we have seen, the normal candle-power is eighty, and a moment's reflection will convince the reader that it would be quite out of the question to make use of an ordinary lamp of this kind in the mouth or indeed in close contact with any part of the body because of the great heat which is generated This difficulty has been surmounted by means of a continuous stream of cold water which circulates within the lamp In the complete equipment, the water is stored in a glass reservoir supported upon a column, down the hollow of which the fluid passes to a flexible tube which carries the stream into the lamp through which it circulates A similar tube carries away the waste water which is ultimately discharged into a vessel at the base of the apparatus

A necessary and most ingenious addition to the ophthalmo-diaphanoscope is the contact signal lamp which is fixed to the column beneath the reservoir, that is to say about on a level with the eyes of the surgeon when he is making an examination of the patient

This lamp lights automatically just before all the water is discharged from the reservoir, so that no matter how much absorbed the surgeon may become in his examination he will be at once apprised that the reservoir is almost empty by a sudden illumination of the darkened chamber He can then at once switch off the current from the lamp, which now that the cooling stream has ceased to flow would become heated and cause discomfort to his patient

It should be added that the outer cover glass of the special lamp is readily removable, so that it may be sterilized after each use Moreover every part of the lamp may be had in duplicate and as these are perfectly interchangeable a broken or faulty part may be at once replaced The whole apparatus has been devised with the utmost care and it is claimed that even those who are unfamiliar with electrical appliances may quickly become accustomed to its use

The ophthalmo-diaphanoscope was specially invented as an aid to diagnosing diseases of the eye, but it has proved of great service in examinations of the throat and nasal cavities while it will probably prove of service to medical science in many other ways. Its chief advantage lies in the fact that an extremely powerful light may be obtained without heat radiation

THE OPHTHALMO-DIAPHANOSCOPE.

* * *

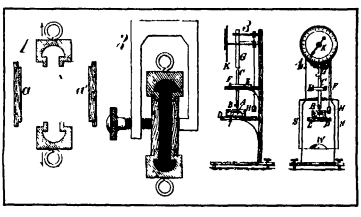
TESTING BITUMENS FOR PAVEMENTS

In every direction the industrial and scientific worlds are endeavoring to measure the properties of substances An instance of this tendency was given in the article on "Testing for Hardness" in the SCIENTIFIC AMERICAN for August 29th 1908 In the present article it is proposed to give some account of measurement efforts in a very different field of activity

The sheet asphalt pavements so common in certain parts of the United States are composed of an admixture of some asphaltic cement and sand It is quite important to have pretty exact information about this bituminous cement in advance of its use in paving mixtures One reason for this is that the cements are by no means all alike. And second the requirements for this use and that vary greatly Thus it comes about that it is a matter of considerable importance to determine the characteristics of samples in course of manufacture or an advance of actual use In fact, since the asphaltic cement is the controlling factor in the mixture used in sheet asphalt paving it is very necessary to make this cement with just the properties suited to the particular case in hand. That is to say, asphaltic cement is a combination of refined asphalt and some tempering oil, as residuum petroleum. It will readily be seen, then, that the properties of the cement will vary with the relative quantities of the two ingredients, to say nothing of the characteristics of the particular asphalt and oil used. For practical purposes, then, it is found very desirable to know in advance whether the cement being made is going to be what is wanted.

There are two principal properties whose determination is sought. These are ductility and viscosity.

In order to measure the ductility, the following method, due to Mr A. W Dow, may be employed: A mold of four pieces is constructed, the plan view of these being shown in Fig 1 These pieces are set up on a brass plate which forms the bottom. The side parts are held in position by a clamp, as shown in Fig. 2 The interior portion of the mold is in the form of a prism, 1 x 1 x 5 centimeters The cement is now poured in, hot of course When cool enough, the top is smoothed off. When the temperature has fallen to the point at which it is desired to make the test, the clamp is loosened, and the two side pieces aa' (Fig 1) are removed We now have a prism of cement held at the sides by clips—the end pieces of the mold By inserting hooks in the eyes of the clips, it is easy to arrange matters so that these clips may be steadily drawn apart This may be accomplished by hand. Mr Dow mentions the rates of separation as 5 centimeters per minute for the temperature of 77 deg. F., and of 1 centimeter per minute for 20 deg. F. It is stated that "it is not safe for an asphalt having a consistency of 40 penetration at 77 deg F to pull less than 20 centimeters at this temperature" What is meant by "a consistency of 40 penetration" will become clear in the sequel



Figs 1 and 2 show mold for sample prism Figs. 3 and 4 show side and front views of the Dow penetrometer.

In order to measure the viscosity (consistency) of a cement, recourse is had to a device for measuring the depth of penetration accomplished by a weighted needle in a given time Prof H C Bowen is said to have invented the pioneer machine about twenty years ago Several devices have been developed since. The one which is probably most in use at the present time was devised by Mr Dow But this latter has now been improved upon by Messrs. Richardson and Forrest.

In the Dow machine, a broad upright rises at the rear of a base, as shown in vertical section in Fig 3. The specimen of asphaltic cement is contained in a small tin box *L* immersed in water in a suitable receptacle. This last rests upon the shelf *D* An aluminium rod *C* is held by a clamp *E*, controlled by a button *F* A No 2 cambric needle *A* is inserted in a brass rod, and this latter is held in position in the aluminium rod by the screw *B* Attached to the aluminum rod *C* is the framework *SS*, Fig 4, carrying a weight *W* It will readily be seen now that by locking the clamp *E* open, by means of the button *F*, the needle, weighted by the parts *C*, *SS*, and *W*, may be brought into contact with the upper surface of the specimen, and allowed to begin penetration

There are two remaining things for which mechanism must be arranged There must be some means of measuring the time and the amount of penetration. The former of these is quite a simple matter A pendulum beating half-seconds is arranged at some convenient point of attachment The second requirement is accomplished as follows In Figs. 3 and 4, *G* is a rack meshing with a pinion back of the dial *K*, and controlling the indicator At the rear end of the spindle carrying the pinion is a drum. A rather thick thread is wound about this drum, and weighted at its lower end by the weight *H* This last is of such amount as just to counterbalance the weight of the rack on the pinion. Consequently, if the lower end of the rack is brought into contact with the aluminium rod *C*, it will not contribute any influence to the penetration of the needle. At the beginning of the test, the lower part of the rack is brought into contact with *C*, and again at the conclusion. The difference in position of the rack will, therefore, give the amount which the needle has

(Concluded on page [illegible])

Pendulum and indicator dial.

TESTING BITUMENS FOR PAVEMENTS.

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

SUPPORT FOR GARMENT-HANGERS.—Fabius Wolf, New York, N Y This support is adapted to be secured beneath a shelf or within a wardrobe, showcase, or the like. The invention relates more particularly to a carrier in which a plurality of rods are used, one being longitudinally movable in respect to the overhead support, and another of the rods being carried by the first-mentioned one and also longitudinally movable in respect thereto, so that the support may be extended to its full length out from beneath the overhead support

Electrical Devices.

TROLLEY-GUARD.—S. G Wilcox North Adams, Mass. The guard is in the form of a spring-pressed slidable plate, nominally extending across the top of the trolley wheel, to prevent it from leaving the trolley wire the plate readily passing the trolley wire hanger and the arrangement permitting withdrawing of the plate by the operator at the same time pulling down the trolley pole

IGNITION APPARATUS—G Haniquet Longbeach, Cal It is sought in this invention to provide means for retaining a thin lubricating oil within a circuit closer In addition the invention comprehends mechanism for reducing the electrical arcking as the contact shoe leaves the contact bar It further contemplates slowing down the speed of the circuit closer shaft, as compared with the main shaft.

INSULATOR.—P S Dumbolton and F Frank, Burke Iowa The invention is more particularly an improvement in insulators mounted on spiral wire coils which are suitably attached to a supporting screw pin It is adapted for lateral oscillation so that it may be used without danger of breaking as is often the case with insulators so fixed on their supports as to be incapable of yielding to jar or vibration.

INDUCTOR DYNAMO—G A Colman Seattle Wash The more particular purpose of the inventor is to produce a dynamo having a minimum of wearing parts and without brushes, collectors, or commutators It relates to the construction of a high-speed rotor having generally the form of a smooth disk made entirely of solid metal, yet heterogeneous as to the magnetic properties.

Of Interest to Farmers.

CULTIVATOR ATTACHMENT—D B Browning, Morrison Okla In operation the fender is supported by the hanger arm and the runner is adjusted a sufficient distance below the edge of the blade to prevent the soil thrown up by the plows from covering the plants, while permitting some soil to be thrown toward the plants at the roots. Engagement of the runner with the ground prevents the fender being moved out of place by the soil thrown up by the plow The runner also permits the fender to fall in with the inequalities of the ground, so as to protect the plants, even when they occupy a lower level than the wheels.

Of General Interest.

TARGET HOLDER—C. P Worrell Zanesville, Ohio The object of this inventor is to provide in connection with the front of the box, clamping strips to bind the edges of the target and laterally adjustable to stretch the target out, and a member closing the rear of the box to check the shot or bullets, the member being preferably in the form of a separable metal plate.

ENVELOP—L. C Van Riper, New York N Y The envelop has an ungummed flap which may be held within a pocket, or removed therefrom in order to allow the contents to be inspected by postal authorities. It is provided with the ordinary gummed flap, intended to be a sealed envelop, and yet allow the same to be sent through the mail at the postage rates required for unsealed matter

FIRE-ESCAPE.—B W Schweimler, Louisville, Ky Here the intention is to provide a device in which a person may be safely transported to the ground from an elevation quickly but without injury It provides an inclined covered chute of zigzag construction. The user is conveyed to the ground while sliding in a sitting posture

SCREEN—F J Rembusch, Shelbyville, Ind In this instance the invention pertains to screens, the more particular purpose being to provide a screen which offers a total obstruction to the passage of light through it, and in this manner improves the distinctness, clearness, and brilliancy of images thrown upon the screen.

SUBMARINE MINE.—A P Broomell, York, Pa. This invention relates to mines in which a mine is connected by a line with an anchor with means for paying out the line and for checking the paying out, so that when the mine and attached anchor are thrown overboard the mine will float as the anchor descends, and as it approaches the bottom it operates to draw the mine below the surface to an extent proportioned to the length of the [illegible] line connected with the anchor.

EXTENSION-BOLT—F H Crump, Los Angeles, Cal. This improvement provides an extensible formed bolt in which the solid bolt [illegible] has a threaded engagement with a hollow internally threaded cylindrical member and [illegible] or sleeve surrounding the two, so that the bolt may be shortened or lengthened by turning the first two mentioned members relatively to each other Further extension of the bolt within reasonable limits may be made by interposing additional threaded sections.

Hardware.

FAUCET—W F Oden Ophir, Utah The faucet is arranged to permit the operator to quickly change the position of the working parts for opening the faucet to the full extent for the removal of a mixture of solid and liquid material or for discharging a mixture of solid and liquid material through a desired sized spout or for completely closing the faucet

LOCKING DEVICE FOR AWNING CORDS OR STRAPS.—S Asch New York N Y This invention is for use in preventing mischievous children having access to awning cords. Means are provided for inclosing and locking up the lower portion of the cord or strap at the point where it is attached. By means of a key access may be had to the interior so as to adjust the awning when desired

Heating and Lighting

FURNACE-GRATE—W J Thomas Salt Lake City Utah The invention relates more particularly to a grate in which the grate bars are utilized as conduits for the delivery of air under pressure to the burning material An object is to so construct the parts that any one of the bars may be removed independently of the other bars and without interrupting the delivery of air through the latter

COMBINED MATCH BOX AND CIGAR CUTTER—E Oldenbusch, New York N Y The box is adapted to receive a card or package of detachably connected friction matches It is formed of two sections movable in respect to each other and one so formed as to frictionally retain the package or card of matches in engagement therewith independently of the other section of the box which constitutes the cover

Household Utilities.

COMBINATION CHAIR AND IRONING BOARD—Rosa Huffy care of C C Harrell Port Arthur Texas An object of this invention is to provide a device which in its normal form constitutes a chair and which can easily be changed from the normal form into a stand such as a table ironing board or the like The invention effects economy of space in a household

CUSPIDOR—M D Green Flora Ill This cuspidor may be hermetically sealed for sterilizing purposes An object is to provide one having a removable receptacle therein and also means whereby a sterilizing or cleansing fluid may be applied thereto A series of cuspidors may be cleansed and sterilized simultaneously

WINDOW SCREEN—F T Peters Lincoln Neb The invention comprises a combination with a casement having sash grooves and pockets in its head and sill the pocket in the head being in alinement with the upper sash of the receiving groove and the one in the sill in alinement with the lower sash both slidable in the groove of a screen resting on the upper sash and movable into and out of the head pocket a screen detachably connected with the lower sash and movable into and out of the sill pocket said pocket having a pan with slidable sections, the lower section being provided with an outlet

TABLE-SLIDE—L. A Wiedeman Louisville Ky In this slide the two side pieces are fastened to the respective halves of the table while the central portion is fastened to the center leg, when the sides are pulled apart the side pieces will slide relatively to the center piece, the latter remaining practically in normal position The table may be extended until the stop members of the slides engage the end top members on the central portion Intervening leaves may then be inserted and will rest upon the upper parts of the slide

Machines and Mechanical Devices.

ADDRESSING MACHINE.—T F Plater Monett, Mo. This inventor seeks to provide the machine with cutting mechanism for severing the strip bearing the addresses and also seeks the provision of means for moistening the strip immediately before it is cut, the strip being provided with a gummed surface to cause the portions severed to adhere to the articles to be addressed.

PORTABLE CONCRETE MIXER—C W Overturf Dumont Iowa One object here is to provide a device in which the time during which the materials are subjected to the mixing process may be varied at will of the operator This is done by means of a mixing cylinder through which the materials pass and which can be inclined to a greater or lesser degree, thereby increasing or decreasing the rate of travel of the charge therethrough.

CASH REGISTER ATTACHMENT—J R. Cosby, Richmond, Va The present invention includes a device operated on and by a key coupler which in turn operates upon the intermediate parts to effect a movement of the advertising mechanism, which may be operated step by step to expose successively the succeeding faces or inscriptions upon the cylinder

GLASS-MOLDING MACHINE—W J Miller, Coffeyville, Kan. This invention relates to semi-automatic glass molding machines in which a table carries a series of molds and is given an intermittent rotary movement through a mechanism including cylinders, and the patentee provides an improved valve arrangement for controlling all the different mechanisms incidental to the several operations of the machine

Prime Movers and Their Accessories.

REVERSING TURBINE—H T Weber New York N Y The turbine is capable of being rotated in either direction The invention resides in the construction of the rotor which enables it to be driven by steam admitted on either side Admitting it on one side drives the rotor in one direction and on the other side drives it in the opposite direction

Railways and Their Accessories.

SIGNALING DEVICE—W I Smith El Paso Texas In its present embodiment the invention comprises a plurality of levers arranged to display signals or be housed within a casing, and mechanism whereby the levers may be locked in either position and also means for locking the operating mechanism Said locking mechanism may be controlled from the cab or other locality occupied by the operator

GRAIN CAR DOOR—J F McGinnis Harvey N D In operation blocks are engaged with their respective plates after which the door is positioned and hinged plates are turned into position against the edges of the door's inner face and locked by pins When the car is to be unloaded the blocks are removed, and the door's lower section swings outward After enough of the load has passed outwardly to relieve the pressure on the upper section the entire door is removed and suspended by hooks

SWITCH ROD—F W Brown Grenada Miss This invention pertains to adjustable switch rods for railroad track switches One intention is to provide a switch rod having shoulders against which the flanges of the switch points may be firmly held thus preventing any lateral movement of the points

RAILWAY TIE—J Butcher Chanute Kan The object in this instance is to provide a construction for ties which facilitates railway construction provide a construction which may be in part or wholly renewed and re used provide a construction which lends itself to varying conditions of railroad construction while being standard in form and provide a construction which cushions the road bed and allows for leveling the same

FASTENING DEVICE FOR INCANDESCENT BODIES—F Stein 26 Wintrfeld Street Berlin Germany The invention pertains to means for fixing the incandescent body and its accessory such as a projecting basket on the burner head or to the frame of a gas lamp for the illumination of railway carriages in connection with which the device is especially intended to be used

Pertaining to Vehicles.

VEHICLE CUSHION—J F Moseman Donaldsonville La The object of this inventor is to provide a device wherein a pneumatic cushion is interposed between the body of the vehicle and the axle The cushion may also be used with railway chairs the legs of the chair resting upon the upper bar and the lower bar being secured to the floor

GRIP THREAD FOR VEHICLE WHEELS—F Holan Niobrara Neb This invention refers to attachment for the rim of a vehicle wheel for the purpose of enabling it to grip the road bed An object is to provide a construction for the device which is simple and which can be readily attached when desired to the wheel

Note.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee title of the invention and date of this paper

---

NEW BOOKS, ETC

Text Book of the History of Architecture. By A D F Hamlin A M Professor of Architecture Columbia University Eighth edition New York Longmans Green & Co 1909 12mo, pp 467, 237 illustrations Price $2

In this work Prof Hamlin has presented an admirably concise sketch of the various periods and styles of architecture and has briefly criticised the more important works of each period or style Despite the fact that extreme condensation in presenting the leading facts has been necessary the work gives a very comprehensive view of the development of architecture Not the least valuable feature of the work is the manner in which technical terms are defined and explained together with a glossary at the end Good judgment has been shown in the selection of the illustrations.

Time and Tide A Romance of the Moon By Sir Robert S Ball LL.D F R S London Society for Promoting Christian Knowledge, 1909 16mo, pp 192 Price $1

This is a reprint of the second edition of "Time and Tide, which consisted originally of a series of lectures delivered before the London Institution The book although popular presumes an acquaintance on the reader's part with such ordinary astronomical facts as may be contained in a work on so difficult a subject of comprehension as the tides If we have any objection whatever to offer against this admirable work it is simply that it is not what is now called up-to-date In other words, we find the subject of solid tides on the earth, that is the displacement of the earth's crust itself not dealt with It seems to us in view of Dr Hecker's recent experimental investigations of this subject and his convincing proof of Sir George Darwin theoretical estimate of the pull on the solid earth that it might have been wise to incorporate in this reprint these later investigations As it is however the book covers the subject well and lucidly

Twenty-five Years of Rope Driving Mishawaka Ind Dodge Manufacturing Company 1909 Quarto

It is not the usual practice of this journal to review in its columns trade publications or catalogues In this particular instance an exception must be made because of the character of the work which lies before us It is not only an example of admirable printing but a good piece of technical compilation In the 101 pages of this book much solid engineering information is given us well as an occasional useful table The material on Features of the American System of Rope Driving Rope Drive Designs American vs English System and Mechanical Power Transmission is particularly good because it seems to state very fairly the main differences between two widely used methods of transmission

Elements of Transportation By Emery R Johnson Ph D New York and London D Appleton & Company, 1909 12mo 360 pages Price $1 50

This is a valuable discussion of steam railroad electric railway and ocean and inland water transportation The author is Professor of Transportation and Commerce in the University of Pennsylvania It has given us great pleasure to review in a short period two other books by Mr Johnson viz American Railway Transportation and Ocean and Inland Water Transportation The volume before this is fully as interesting and these three books should be in the library of every person who wishes to keep fully apace with the times. The author's vast experience has enabled him to handle the subject in a masterly manner The maps are particularly valuable many of them being printed in both red and black showing the increase in mileage at various periods, and also the maps showing the various so-called routes

Die Haus und Hotel Telegraphie und Telephonie Von O Canter Dritte gänzlich neubearbeitete Auflage Von Paul Riemenschneider 1 3 Illustrations Octavo Vienna A Hartleben 1909

The book which lies before us has passed into its third edition It is a text book for those electricians who are concerned with the installation of house telephone and telegraph systems Since such electricians are not always technically trained men the author begins the book with the usual popular discussion of the cause and effect of the galvanic current electromagnetism and induction Then follows a description of the apparatus employed which description is as exhaustive as possible and deals with the underlying theories of each part thoroughly After a discussion of the simple and most common house telegraph apparatus namely alarms of various constructions with their accompanying circuits we find discussion of annunciator systems and telephone and microphone inventions The subject of house telephony is described at length as well as suitable protective devices against atmospheric electricity Interesting is a discussion of telltale door contacts clock contacts fire alarms etc After describing the material necessary for the installation of a house telephone or telegraph system the author passes to the manner of installing the systems described and testing methods for the detection of injured portions The estimate of cost given would hardly apply in this country but serve the purpose at least of showing the relative value of different parts

The Force of the Wind By Herbert Chatley 80 pp 12mo Ill with diagrams London Charles Griffin & Co 1909 Imported by Lippincott Price $1 25

We find in this little book collected and correlated methods of calculation of wind stresses and wind power which we have often sought with difficulty from scattered formulæ in engineering pocket books and text books and believe that it will fill a long felt want among engineers who have to deal with wind load on structures and similar problems The formulæ many of which are derived by the author are as simple as moderate accuracy will permit and algebraic methods are introduced only where it is impossible to avoid them The book is thoroughly up to date including the latest results obtained by Lanchester and Eiffel and is throughout clear and practical

Coordinate Geometry By H B Fine and H D Thompson 300 pp 12mo 9 plates. New York The Macmillan Company 1909 Price $1 60

In this book the several conic sections are treated early and in some detail partly because of the value of a knowledge of their more im portant properties, partly because of the advantage when presenting the analytic method to the student, of applying it in the first instance in the systematic study of a few interesting curves. In deference to usage, a chapter on the circle is introduced immediately after that on the straight line, but if experience is to be trusted it is better in a first course to proceed from the straight line directly to the parabola so that as early as possible the student may get the impression which comes from seeing a method employed in the investigation of new material. The part of the book devoted to solid geometry is more extended than is customary in elementary text books but it is desirable that the material here given should be easily accessible to students. Although intended as a college textbook the present work follows the fortunate modern tendency toward the practical and forms as good a treatise upon the subject as possible for the non collegiate student.

A MANUAL OF PRACTICAL ASSAYING. By the late H van F Furman. Revised and enlarged by W D Pardoe. 497 pp 8vo New York John Wiley & Sons 1909 Price $3

This standard work on assaying has, in the new (sixth) edition been thoroughly revised and brought up to date. The chapters on zinc water and coal analyses have been rewritten and minor changes have been made in certain parts due to the description of new methods. Because of their increasing importance commercially chapters have been added on the assay of telluride ores tungsten molybdenum, and vanadium. On the latter important subjects the reputation of the work as one of the leading text books on the subject has been completely maintained and the usefulness of the whole enhanced.

STRUCTURAL DETAILS. Elements of Design of Heavy Framing. By H S Jacoby. 368 pp 8vo 6 folding plates and 34 full page ill New York John Wiley & Sons, 1909 Price $2 25

The title of this volume corresponds to a course of instruction conducted by the author in the College of Civil Engineering in Cornell University during the past nineteen years. In this course the students receive their first instruction in the application of the principles of mechanics to the design of the details of structures. Experience has shown that in many respects problems involving timber construction are better adapted for this purpose than if confined to structural steel. It may appear at first as if too much attention to details is given in the examples on the design of joints beams and trusses. The author believes however that the importance of careful study of every detail can only thus be properly emphasized. In practice it seems to be the exception rather than the rule to give the same attention to details of timber structures as to those of steel. In the interest of sound engineering practice it is essential that all connections and details have the same degree of security as the framed members. In several articles the order of design is given in full with a view of economising the time of the student and of promoting systematic habits in making the computations required these objects being regarded as important elements in efficient engineering education and practice. Whereas the book is intended for college use much of it is so written as to be intelligible without the mathematics involved and valuable to the practical carpenter or builder desirous that his work shall be on sound principles or interested in the theory upon which are founded the rules of his practice.

THE INTERNAL COMBUSTION ENGINE. By H E Wimperis. 320 pp 8vo, fully ill New York D Van Nostrand Company 1909 Price $3

This is the first treatise on gas oil and gasoline engines we have seen which goes as thoroughly into the subject both theoretically and practically as do the best text books on the steam engine. The author traces the energy that drives our engines all the way from solar heat and molecular action to the uses to which the modern internal combustion engine is applied covering sufficiently the laws of thermodynamics the chemistry of combustion and explosion the best design in gas engines and producers and oil and gasoline engines. The final chapter on gasoline engine efficiency and rating is the best we have seen on this much debated question and is in so far practical and helpful to the amateur and the sportsman as to discuss the modification of accepted ratings which should be made in hill climbing and other automobile competitions.

HENRY HUDSON. A Brief Statement of His Aims and Achievements. By Thomas A Janvier. To which is added a newly discovered partial record now first published of the trial of the mutineers by whom he and others were abandoned to their death. New York and London Harper & Bros 148 pp, 12 ill, 16mo Price 75 cents.

The Hudson Fulton Celebration has aroused keen interest in the life of one of the most romantic characters among the explorers and navigators of the sixteenth and seventeenth centuries. The book before us is divided into two parts, the first consisting of a brief sketch of the life of Henry Hudson and the second dealing with newly-discovered documents. The latter have remained neglected for three centuries, and are here published for the first time. The discovery of these documents is due to Dr R G. Marston, M.A., as a result of a search in the Record Office in London. The story of the trial is of great interest, but of little satisfaction, inasmuch as we are ignorant of what punishment, if any, was inflicted upon the mutineers of the "Discovery." The importance of these documents is that they establish the fact (until now not established) that the mutineers were brought to trial, and that they embody a sworn testament, hitherto unproduced, of six members of Hudson's crew concerning the mutiny. The illustrations include no portrait of Hudson since the author is satisfied that no authentic portrait of the man is in existence. Outside of the new documentary evidence above referred to, the narrative of Hudson's life is a condensation of the facts that have been recorded by Hudson's authoritative biographers, notably Purchas, Gerrits Van Meteren, Asher, Murphy, Brodhead, and Read.

MACHINE SHOP DRAWINGS. Reading Drawings, Making Shop Sketches, and Laying Out Work. By Fred H Colvin, A.S.M.E. F.I. New York McGraw, Hill Book Company, 1909 16mo, 139 pp Price, $1.

This little book is intended to be a help to those who do not thoroughly understand the reading of drawings, rather than an attempt to teach drawing in itself. It shows how seen and unseen portions are represented, the use of full and dotted lines, the way in which different views are drawn and how to study them all so as to secure a correct idea of the shape of the piece represented. Many actual examples are given from the drawing-room practice of the leading shops in this country and the meaning of each carefully explained. The book is an eminently practical one and is illustrated by well-executed engravings, the wax process, which is the only suitable one for the purpose, being used.

A Book of Fourth-Dimension Essays.

The subject of the fourth dimension seems to have aroused so much interest among the readers of the SCIENTIFIC AMERICAN that we have decided to publish in book form the prize essay the three essays that received honorable mention and about sixteen of the best essays which were submitted in the recent Fourth Dimension Contest. The entire collection will be edited by Prof H P Manning who will prepare an introduction of considerable length in which the subject of the fourth dimension will be simply and lucidly discussed. The book will be ready about the latter part of December.

Legal Notices

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

INDEX OF INVENTIONS

For which Letters Patent of the United States were issued for the Week Ending

October 26, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Account register, Claudt & Beidt	938,214
Acid derivative guaiacol carbonate sulfo, A Einhorn	938,172
Acid derivative of aminoarylamide, Ehrlich & Bertheim	937 929
Advertising device, J E Downing	938,225
Agglomerating machine, O Crochet	938,217
Agricultural machine seat adjusting mechanism, J Bard	937 982
Air and steam coupling automatic, J V Baldwin	937,961
Air brake, L E Morel	937,859
Air brake systems angle cock support and lock for, W F Sharp, reissue	13,029
Air compressor and intercooler combined, J G Leyner	938,004
Air inlet fresh, R R Henry	938,146
Air ship, W C Perry	937 956
Air supply device fresh, F R Tippitt	937 927
Air through barrels pneumatic system for circulating, J F McLain	938,014
Alloy metallic, O Hartmann	938,422
Alumina manufacture of, G McCulloch	938,289
Alumina recovery of soda in the manufacture of, H C Peffer	938,376, 938,432
Automobile brake, F F Lithander	[illegible]
Automobile [illegible], J J Tibbs	[illegible]
Automobile [illegible] Jackson	[illegible]
Automobile [illegible], F P Foote	[illegible]
Ankle brace, F J [illegible]	[illegible]
Apparel attachment, wearing, A [illegible]	[illegible]
